

Upper-bound of Reduction Operators

and Computation of Syzygies

Cyrille Chenavier

1 Introduction

Several constructive methods in algebra are based on the computation of syzygies. For instance, a generating set of syzygies offers criteria to detect useless critical pairs during Buchberger's algorithm, that is critical pairs whose corresponding S -polynomials reduces into zero [8]. Such criteria improve the complexity of Buchberger's algorithm since most of the time is spent in computing into zero. Another application scope is homological/homotopical algebra where syzygies enable us to construct resolutions of monoids or algebras [1, 6, 7]. Several methods for computing syzygies were introduced: Squier's theorem states that the module of syzygies of a convergent string rewriting system is spanned by confluence diagrams [9, 10], which imply that syzygies can be computed by a completion-reduction procedure [5]. Moreover, the syzygies of a regular sequence are spanned by principal syzygies [4]. In [2], a general method for computing syzygies of a set of polynomial equations is given.

In this work, we are interested in the computation of syzygies of linear rewriting systems. Our motivation is to develop a general framework which can be specialised to various structures whose underlying sets of terms are vector spaces: polynomial algebras, tensor algebras, Lie algebras, operads... We fix a vector space V and a basis G of V : when V is a polynomial algebra, G is the set of monomials, for tensor algebras, G is the set of words, for instance. We consider linear rewriting systems described by *reduction operators*. Given a well-order $<$ on G , a reduction operator is an idempotent endomorphism of V such that for every $g \notin \text{im}(T)$, $T(g)$ is a linear combination of elements of G strictly smaller than g for $<$. Such an operator encodes the reductions

$$v \xrightarrow{T} T(v),$$

for every vector $v \notin \text{im}(T)$.

Given a set $F = \{T_1, \dots, T_n\}$ of reduction operators, the syzygies of F are the elements of the kernel of the map

$$\begin{aligned} \pi_F : \ker(T_1) \oplus \dots \oplus \ker(T_n) &\longrightarrow V. \\ (v_1, \dots, v_n) &\longmapsto \sum_{i=1}^n v_i \end{aligned}$$

In [3, Proposition 2.1.14], it is shown that the set of reduction operators admits a lattice structure. Our method for constructing a linear basis of $\mathbf{Syz}(F)$ works as follows: $\mathbf{Syz}(f_1, f_2)$ is isomorphic to the kernel of the upper bound $T_1 \vee T_2$ of T_1 and T_2 . Moreover, for every integer $2 \leq k \leq n-1$, we have onto morphisms:

$$\begin{aligned} \mathbf{Syz}(T_1, \dots, T_{k+1}) &\longrightarrow \mathbf{Syz}(T_1 \wedge \dots \wedge T_k, T_{k+1}), \\ (v_1, \dots, v_{k+1}) &\longmapsto \left(\sum_{i=1}^k v_i, v_{k+1} \right) \end{aligned}$$

where $T_1 \wedge \dots \wedge T_k$ is the lower bound of $\{T_1, \dots, T_k\}$. Hence, if a linear basis \mathcal{B}_k of $\mathbf{Syz}(T_1, \dots, T_k)$ is known, we construct a linear basis of $\mathbf{Syz}(f_1, \dots, f_{k+1})$ by taking the union of \mathcal{B}_k with pre-images of elements of a linear basis of $\mathbf{Syz}(T_1 \wedge \dots \wedge T_k, T_{k+1})$. This method provides successively linear bases of $\mathbf{Syz}(T_1, T_2)$, $\mathbf{Syz}(T_1, T_2, T_3)$, ..., $\mathbf{Syz}(T_1, \dots, T_n) = \mathbf{Syz}(F)$.

2 Reduction Operators

2.1. Notations. We fix a well-ordered set $(G, <)$ and a commutative field \mathbb{K} . Every vector v of the vector space $\mathbb{K}G$ spanned by G admits a greatest element, written $\text{lg}(v)$, in its decomposition with respect to G . We extend the order $<$ on G into an order on $\mathbb{K}G$ defined by $v_1 < v_2$ if $v_1 = 0$ and $v_2 \neq 0$ or if $\text{lg}(v_1) < \text{lg}(v_2)$.

2.2. Definition. A linear endomorphism T of $\mathbb{K}G$ is called a *reduction operator* if it is a projector and if for every $g \in G$, we have $T(g) \leq g$. We write $\mathbf{RO}(G, <)$ the set of reduction operators and for every $T \in \mathbf{RO}(G, <)$, we write

$$\text{Red}(T) = \{g \in G \mid T(g) \neq g\}.$$

2.3. T -decompositions. A reduction operator being a projector, the kernel of T admits as a basis the set of $g - T(g)$, where g belongs to $\text{Red}(T)$, that is every $v \in \ker(T)$ admits a unique decomposition

$$v = \sum_{g \in \text{Red}(T)} \lambda_g (g - T(g)). \quad (1)$$

The decomposition (1) is called the *T -decomposition* of v .

2.4. Lattice Structure. Recall from [3, Proposition 2.1.14] that the map

$$\begin{aligned} \ker : \mathbf{RO}(G, <) &\longrightarrow \{\text{subspaces of } \mathbb{K}G\}, \\ T &\longmapsto \ker(T) \end{aligned}$$

is a bijection. Given a subspace V of $\mathbb{K}G$, we write $\ker^{-1}(V)$ the unique reduction operator with kernel V . Then, $(\mathbf{RO}(G, <), \preceq, \wedge, \vee)$ is a lattice where

- i. $T_1 \preceq T_2$ if $\ker(T_2) \subseteq \ker(T_1)$,
- ii. $T_1 \wedge T_2 = \ker^{-1}(\ker(T_1) + \ker(T_2))$,
- iii. $T_1 \vee T_2 = \ker^{-1}(\ker(T_1) \cap \ker(T_2))$.

3 Syzygies

We fix a subset $F = \{T_1, \dots, T_n\}$ of $\mathbf{RO}(G, <)$ and we let

$$\ker(F) = \ker(T_1) \oplus \dots \oplus \ker(T_n).$$

An element of $\ker(F)$ is written (v_1, \dots, v_n) , where each v_i belongs to $\ker(T_i)$.

3.1. Notation. For every integer $1 \leq i \leq n$ and for every $g \in \text{Red}(T_i)$, we let

$$b_{i,g} = (0, \dots, 0, g - T_i(g), 0, \dots, 0).$$

The set

$$\mathcal{B} = \{b_{i,g} \mid 1 \leq i \leq n \text{ and } g \in \text{Red}(T_i)\},$$

is a linear basis of $\ker(F)$.

3.2. Definition. Consider the linear map

$$\begin{aligned} \pi_F : \ker(F) &\longrightarrow \ker(\wedge F). \\ (v_1, \dots, v_n) &\longmapsto \sum_{i=1}^n v_i \end{aligned}$$

We write

$$\mathbf{Syz}(F) = \ker(\pi_F).$$

The elements of $\mathbf{Syz}(F)$ are called the *syzygies* of F .

3.3. Canonical Decompositions. By definition of syzygies, we have a linear isomorphism

$$\overline{\pi_F} : \ker(F) / \mathbf{Syz}(F) \xrightarrow{\sim} \ker(\wedge F).$$

Moreover, $\ker(F) / \mathbf{Syz}(F)$ admits as a basis a subset $\mathcal{B}(F)$ of \mathcal{B} , so that

$$\left\{ g - T_i(g) \mid b_{i,g} \in \mathcal{B}(F) \right\}, \quad (2)$$

is a basis of $\ker(\wedge F)$. The decomposition of an element v of $\ker(\wedge F)$ with respect to (2) is called a *canonical decomposition* of v with respect to F .

3.4. Remark. Following the terminology of [3, Section 2.1.9], $\mathcal{B}(F)$ can be chosen in such a way that it is also *reduced* and this choice is unique, which motivates the terminology of "canonical basis". In the sequel, we do not assume that $\mathcal{B}(F)$ is reduced.

3.5. Purpose. Our purpose is to introduce an algorithm for computing $\mathbf{Syz}(F)$. This algorithm is based on the fact that for every family U_1, \dots, U_k of reduction operators, we have a linear map:

$$\begin{aligned} \mathbf{Syz}(U_1, \dots, U_k) &\longrightarrow \mathbf{Syz}(U_1 \wedge \dots \wedge U_{k-1}, U_k). \\ (v_1, \dots, v_k) &\longmapsto \left(\sum_{i=1}^{k-1} v_i, v_k \right) \end{aligned}$$

We also need the following:

3.6. Proposition. Let $P = (T_1, T_2)$ be a pair of reduction operators. We have a linear isomorphism

$$\begin{aligned} \ker(T_1 \vee T_2) &\xrightarrow{\sim} \mathbf{Syz}(P). \\ v &\longmapsto (-v, v) \end{aligned}$$

3.7. The Algorithm. The algorithm takes as input a finite subset $F = \{T_1, \dots, T_n\}$ of $\mathbf{RO}(G, <)$ and returns a basis of $\mathbf{Syz}(F)$.

Algorithm 1 Computation of a Basis of Syzygies

Initialisation:

- $T := \text{Id}_{\mathbb{K}G}$;
- $v := 0$;
- $B := \emptyset$.

```

1: for  $i = 2$  to  $n$  do
2:    $T = T_1 \wedge \dots \wedge T_{i-1}$ ;
3:   for  $g_0 \in \text{Red}(T \vee T_i)$  do
4:      $v = g_0 - (T \vee T_i)(g_0)$ ;
5:      $\sum \lambda_g (g - T_i(g))$  : the  $T_i$ -decomposition of  $v$ ;
6:      $\sum \lambda_{j,g'} (g' - T_j(g'))$  : a canonical decomposition of  $v$  with respect to  $(T_1, \dots, T_{i-1})$ ;
7:      $B = B \cup \left\{ \sum (\lambda_g b_{i,g}) - \sum (\lambda_{j,g'} b_{j,g'}) \right\}$ ;
8:   end for
9: end for
10: return  $B$ 

```

4 Example

We consider $G = (g_1 < g_2 < g_3 < g_4 < g_5 < g_6)$. We let $F = \{T_1, T_2, T_3, T_4\}$, where the operators T_i are defined by their matrices with respect to the basis G :

$$T_1 = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \quad T_2 = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$T_3 = \begin{pmatrix} 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad T_4 = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}.$$

The vector space $\ker(F)$ is spanned by the following eight vectors:

$$b_1 = (g_4 - g_3, 0, 0, 0), \quad b_2 = (g_5 - g_3, 0, 0, 0), \quad b_3 = (g_6 - g_1, 0, 0, 0), \quad b_4 = (0, g_4 - g_2, 0, 0)$$

$$b_5 = (0, g_5 - g_2, 0, 0), \quad b_6 = (0, g_6 - g_2, 0, 0), \quad b_7 = (0, 0, g_4 - g_1, 0), \quad b_8 = (0, 0, 0, g_5 - g_1).$$

We describe the algorithm of the previous section to compute a linear basis B of $\mathbf{Syz}(F)$. We begin with $B = \emptyset$.

4.1. Step 1. We have

$$T_1 \vee T_2 = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}.$$

The set $\text{Red}(T_1 \vee T_2)$ is reduced to $\{g_5\}$ and $g_5 - (T_1 \vee T_2)(g_5)$ is equal to $g_5 - g_4$. We have

$$g_5 - g_4 = (g_5 - g_3) - (g_4 - g_3)$$

$$= (g_5 - T_1(g_5)) - (g_4 - T_1(g_4)),$$

and

$$g_5 - g_4 = (g_5 - g_2) - (g_4 - g_2)$$

$$= (g_5 - T_2(g_5)) - (g_4 - T_2(g_4)).$$

We have

$$B = \{b_5 - b_4 - b_2 + b_1\}.$$

4.2. Step 2. We have

$$(T_1 \wedge T_2) \vee T_3 = \begin{pmatrix} 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}.$$

We need to determine the T_3 -decomposition of $g_4 - g_1$ and well as a canonical decomposition of $g_4 - g_1$ with respect to (T_1, T_2) . These two decompositions are given by

$$\begin{aligned} g_4 - g_1 &= g_4 - T_3(g_4) \\ &= -(g_6 - g_2) + (g_4 - g_2) + (g_6 - g_1) \\ &= -(g_6 - T_2(g_6)) + (g_4 - T_2(g_4)) + (g_4 - T_1(g_4)), \end{aligned}$$

so that, we have

$$B = \{b_5 - b_4 - b_2 + b_1, b_7 + b_6 - b_4 - b_3\}.$$

4.3. Step 3. We have

$$(T_1 \wedge T_2 \wedge T_3) \vee T_4 = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}.$$

The T_4 -decomposition of $g_5 - g_1$ and a canonical decomposition of $g_5 - g_1$ with respect to (T_1, T_2, T_3) are given by

$$\begin{aligned} g_5 - g_1 &= g_5 - T_4(g_5) \\ &= -(g_6 - g_2) + (g_4 - g_2) + (g_6 - g_1) + (g_5 - g_3) - (g_4 - g_3) \\ &= -(g_6 - T_2(g_6)) + (g_4 - T_2(g_4)) + (g_6 - T_1(g_6)) + (g_5 - T_1(g_5)) - (g_4 - T_1(g_4)), \end{aligned}$$

so that, we have

$$B = \{b_5 - b_4 - b_2 + b_1, b_7 + b_6 - b_4 - b_3, b_8 + b_6 - b_4 - b_3 - b_2 + b_1\}.$$

4.4. Remark. The syzygies $\mathbf{Syz}_1 = b_5 - b_4 - b_2 + b_1$, $\mathbf{Syz}_2 = b_7 + b_6 - b_4 - b_3$ and $\mathbf{Syz}_3 = b_8 + b_6 - b_4 - b_3 - b_2 + b_1$ have the following geometric interpretations:
