1 Introduction and motivation

In the following, one shall prove *strong normalization of system F* using a proof technique known as *realizability*. This approach was initiated by Kleene and developed further by many, notably by Krivine (especially beyond the intuitionistic setting by developing a framework of realizability for classical logic, known as *classical realizability*).

One will consider Curry-style system **F**: we will work with pure λ -terms and show that every term that is typable is strongly normalizing. We will deduce strong normalization of Church-style system **F** thanks to the equivalence established in the previous chapter.

Realizability is in fact a much wider, flexible and powerful tool that allows to analyze the computational behaviour of terms from information on their types in a fine-grained way, beyond (strong) normalizability properties as one shall see on some examples.

Before coming to the realizability construction, let us begin with a remark on normalization proofs by reducibility.

To analyze normalization properties in this setting, one had to express *stability properties by argument application* (or universal instantiation in **F**, more generally by the effect of the destructors of the language as in **T**), for instance defining:

$$\text{RED}^{\text{WN}}_{\rho}(U \rightarrow V) = \{t : (U \rightarrow V)^{\rho} \mid \forall u \in \text{RED}^{\text{WN}}_{\rho}(U), (t)u \in \text{RED}^{\text{WN}}_{\rho}(V)\}.$$

that one can see as a special case of a more general construction:

$$\mathcal{X} \rightarrow \mathcal{Y} = \{t/\forall u \in \mathcal{X}, (t)u \in \mathcal{Y}\}$$

which gives:

$$\begin{aligned} \text{RED}^{\text{WN}}_{\rho}(U \rightarrow V) &= \{t : (U \rightarrow V)^{\rho} \mid \forall u \in \text{RED}^{\text{WN}}_{\rho}(U), (t) u \in \text{RED}^{\text{WN}}_{\rho}(V)\} \\ &= \text{RED}^{\text{WN}}_{\rho}(U) \rightarrow \text{RED}^{\text{WN}}_{\rho}(V). \end{aligned}$$

In particular, in the simply typed case for instance, every type T is of the form: $T = U_1 \rightarrow \dots \rightarrow (U_n \rightarrow X)$ where X is a type variable. By noting that for type variables, one set $\rho(X) = \text{Norm}(X)$, one thus has, in this case:

$$\text{RED}^{\text{WN}}_{\rho}(T) = \{t : T^{\rho} \mid \forall i \leq n, \forall u_i \in \text{RED}^{\text{WN}}_{\rho}(U_i), (t) u_1 \dots u_n \in \text{Norm}(X)\}$$

One shall generalize these reducibility techniques by evidencing the central notion of applicative context: $(\square)u_1 \dots u_n$ that one shall manipulate through the notion of stacks which give to applicative contexts a *first-class* existence.

Definition 1.1 ((Applicative) contexts)

Contexts and applicative contexts are defined inductively as follows:

$$\begin{aligned} C &::= \square \mid \lambda x.C \mid (t)C \mid (C)t \\ A &::= \square \mid (A)t \end{aligned}$$

2 Realizability interpretation

Let us consider Curry-Style System F: λ -terms are untyped terms and one considers a ternary typability relation, $\vdash_{\text{F}} \subseteq \text{Env} \times \Lambda \times \text{Type}_{\text{F}}$, written $\Gamma \vdash_{\text{F}} t : T$.

Definition 2.1 (Stacks)

Let us note Π the set of **stacks**, defined inductively by:

$$\pi, \pi' ::= \emptyset \mid t \cdot \pi.$$

Π is therefore the set of finite sequences of λ -terms,

Definition 2.2 (Processes)

A **process** is a pair of a λ -term and a stack.
The process (t, π) may also be written $t \star \pi$.
We write $\text{P} = \Lambda \times \Pi$ for the set of processes.

Example 2.3

One can for instance consider process $(\lambda x.(x)x, \lambda y.(y)y \cdot \emptyset)$.

Definition 2.4 (Pole)

Given a set of terms Λ_0 containing the variables, a Λ_0 -**pole** is a subset \perp of P satisfying following two properties of closure by anti-reduction with respect to Λ_0 :

1. If $(t \{u/x\}, \pi) \in \perp$ and $u \in \Lambda_0$, then $(\lambda x.t, u \cdot \pi) \in \perp$.
2. If $(t, u \cdot \pi) \in \perp$ then $((t) u, \pi) \in \perp$.

One shall simply speak of a pole in the following, when this is not ambiguous.

Remark 2.5

For those who know the Krivine Abstract Machine (KAM), they will note that the previous properties correspond to closure by anti-reduction of the KAM for arguments in Λ_0 .

Example 2.6

The reader is invited to check that the following sets of processes are poles:

- $\emptyset, \Lambda \times \Pi$ are poles for any choice of Λ_0 (satisfying the minimal conditions on Λ_0).
- $\{(t, \pi) \in P \mid (t)\pi \in \Lambda_{SN}\}$ is a Λ_{SN} -pole. (see section on the applications of realizability to strong normalization.)
- Let Λ_0 containing the variables, $\{(t, \pi) \mid (t)\pi \rightarrow^* \lambda x.x\}$ is a Λ_0 -pole.

Given a pole (ie a Λ_0 -pole for a certain Λ_0), one can relate sets of terms and sets of staks by a so-called **orthogonality** relation:

Definition 2.7 (Orthogonality)

Let \perp be a pole. Let T be a set of terms and F a set of stacks. One defines T^\perp and F^\perp in the following way:

$$T^\perp = \{\pi \in \Pi \mid \forall t \in T, (t, \pi) \in \perp\} \quad F^\perp = \{t \in \Lambda \mid \forall \pi \in F, (t, \pi) \in \perp\}.$$

This orthogonality relation satisfies, straightforwardly, the following properties which are left to the reader as an exercise:

Proposition 2.8

- $T \subseteq U \Rightarrow U^\perp \subseteq T^\perp$;
- $T \subseteq T^{\perp\perp}$;
- $T^\perp = T^{\perp\perp\perp}$.

Reducibility was built by defining sets of λ -terms by induction on type. Here, one shall define **sets of stacks** by induction on type and build sets of terms by orthogonality:

Definition 2.9 (Π_0)

Given a Λ_0 -pole \perp , Π_0 denotes the set of stacks built from elements of Λ_0 .

Definition 2.10 (Valuation)

Given a Λ_0 -pole \perp , a **valuation** ν is a function from type variables to subsets of Π_0 .

Given a valuation ν , X a type variable and $F \subseteq \Pi_0$, $\nu[X := F]$ is defined as the valuation equal to F on X and equal to ν on any other type variable.

Definition 2.11 (Interpretation of a type, falsity value)

Given a Λ_0 -pole \perp and a valuation ν , one defines inductively the interpretation $\| _ \|_\nu$ of F-types (taking values in the subsets of Π) as follows:

- $\|X\|_\nu = \nu(X)$;
- $\|A \Rightarrow B\|_\nu = \{t \cdot \pi \mid t \in \|A\|_\nu^\perp, \pi \in \|B\|_\nu\}$;
- $\|\forall X.A\|_\nu = \cup_{F \subseteq \Pi_0} \|A\|_{\nu[X:=F]}$.

$\|T\|_{\mathbf{v}}$ will be called **the falsity value** of T .

Definition 2.12 (Realizability relation, truth value)

Given a Λ_0 -pole \perp and a valuation \mathbf{v} , a term t **realizes** a type T , written $t \Vdash_{\mathbf{v}} T$, if $t \in \|T\|_{\mathbf{v}}^{\perp}$. Such a t is called a **realizer** of T .

The set of realizers of T is written $|T|_{\mathbf{v}}$; it is equal to the orthogonal of $\|T\|_{\mathbf{v}}$ and will be called the **truth value** of T .

The following remark provides an intuition for the terminology of truth/falsity values.

Remark 2.13 (Truth and falsity values)

Realizability has two parameters: the pole and the valuation (there is actually a third parameter, the set Λ_0), even though only the pole is shown in the notation.

Whatever choice we make of Λ_0 , \emptyset and $\mathsf{P} = \Lambda \times \Pi$ are poles. In the case where $\perp = \emptyset$, one has

$$F^{\perp} = \begin{cases} \Lambda & \text{si } F = \emptyset \\ \emptyset & \text{si } F \neq \emptyset \end{cases} .$$

One therefore recovers the usual boolean interpretation:

- $|A \rightarrow B|_{\rho} = \emptyset$ if $|A|_{\rho} = \Lambda$ and $|B|_{\rho} = \emptyset$ et
- $|A \rightarrow B|_{\rho} = \Lambda$ otherwise.

In the same way:

- $|\forall X.A|_{\rho} = \emptyset$ if there exists $F \in F_{\Lambda_0}$ such that $|A|_{\rho[X:=F]} = \emptyset$ and
- $|\forall X.A|_{\rho} = \Lambda$ otherwise.

This is from this interpretation that come the names **truth value** and **falsity values** as one easily understands.

One establishes a first property of the above constuctions, a classical substitutivity property which looks alike a property established for reducibility.

Lemma 2.14 (Substitutivity of the realizability interpretation)

For any types T, U and any type variable X , one has for every pole and every valuation \mathbf{v} that:

$$\|T\{U/X\}\|_{\mathbf{v}} = \|T\|_{\mathbf{v}[X:=\|U\|_{\mathbf{v}}]}.$$

Proof: The lemma is proved by induction on the structure of the type, writing $\mathbf{v}' = \mathbf{v}[X := \|U\|_{\rho}]$.

- Case $T = X$ is trivial.
- Case $T = Y \neq X$ is trivial.
- Case $T = V \rightarrow W$: one has $T\{U/X\} = V\{U/X\} \rightarrow W\{U/X\}$, so that a stack π belongs to $\|T\{U/X\}\|_{\mathbf{v}}$ if, and only if, it is of the form $t \cdot \pi'$ where $t \in |V\{U/X\}|_{\mathbf{v}} = \|V\{U/X\}\|_{\mathbf{v}}^{\perp}$ and $\pi' \in \|W\{U/X\}\|_{\mathbf{v}}$, or, thanks to the induction hypothesis if, and only if, $t \in \|V\|_{\mathbf{v}'}$ and $\pi' \in \|W\|_{\mathbf{v}'}$, that is iff $t \cdot \pi \in \|T\|_{\mathbf{v}'}$.
- Case $T = \forall Y.V$ (with $Y \neq X$ and $Y \notin FV(U)$): one has $T\{U/X\} = \forall Y.(V\{U/X\})$ and thus $\pi \in \|T\{U/X\}\|_{\mathbf{v}}$ if, and only if, $\pi \in \|V\{U/X\}\|_{\mathbf{v}[Y:=F]}$ for some F in F_{Λ_0} and, applying the induction hypothesis as above, if and only if $\pi \in \|V\|_{\mathbf{v}'[Y:=F]}$ for some F in F_{Λ_0} , that is if and only if $\pi \in \|T\|_{\mathbf{v}'}$.

This concludes the proof. □

Lemma 2.15

If \mathbf{v} is such that for any T , $\|T\|_{\mathbf{v}} \subseteq \Pi_0$ and if $F \subseteq \Pi_0$, then $\mathbf{v}' = \mathbf{v}[X := F]$ is also such that for any T , $\|T\|_{\mathbf{v}'} \subseteq \Pi_0$.

Proof: Indeed, $\|T\|_{\mathbf{v}'} \subseteq \|\forall X.T\|_{\mathbf{v}} \subseteq \Pi_0$. □

3 Adequation lemma (Adequacy lemma)

One shall prove an adequation result of the realizability semantics to the typing.

For this, one defines two specific sorts of valuations:

Definition 3.1 (weakly/well adapted valuations)

A valuation \mathbf{v} is **weakly adapted** to a Λ_0 -pole \perp if, for any type T ,

$$|T|_{\mathbf{v}} \subseteq \Lambda_0 \quad \& \quad \|T\|_{\mathbf{v}} \subseteq \Pi_0.$$

A valuation \mathbf{v} is **adapted** (or *well-adapted*) to a Λ_0 -pole \perp if, for any type T ,

$$\mathcal{V} \subseteq |T|_{\mathbf{v}} \subseteq \Lambda_0 \quad \& \quad \|T\|_{\mathbf{v}} \subseteq \Pi_0.$$

A well-adapted valuation is therefore a weakly adapted valuation such that variables realize every type.

Remark 3.2

If one considers a realizability construction with $\Lambda_0 = \Lambda$, then every valuation is trivially weakly adapted.

Definition 3.3 (Admissible set of terms)

A set $\Lambda_0 \subseteq \Lambda$ is **admissible** if there exists a Λ_0 -pole \perp and a valuation \mathbf{v} which is well-adapted for \perp .

One can now state the adequation lemma for realizability:

Lemma 3.4 (Adequation lemma)

Let \mathbf{v} be a valuation for a pole \perp such that for any type U , $\|U\|_{\mathbf{v}} \subseteq \Pi_0$, and let t be a term such that $x_1 : U_1, \dots, x_n : U_n \vdash_{\mathbf{F}} t : T$ is derivable in Curry-Style \mathbf{F} . Let $(u_i)_{1 \leq i \leq n}$ be realizers of the $(U_i)_{1 \leq i \leq n}$ (ie. $u_i \Vdash_{\mathbf{v}} U_i$ for $1 \leq i \leq n$), then $t \{u_i/x_i, 1 \leq i \leq n\} \Vdash_{\mathbf{v}} T$.

Proof: One proves the lemma by induction on a typing derivation d of $x_i : U_i \vdash_{\mathbf{F}} t : T$. (Note that there may exist several such typing derivations since we work with Curry-Style System \mathbf{F} ...) One shall write $\Gamma = x_1 : U_1, \dots, x_n : U_n$ and $t' = t \{u_i/x_i, 1 \leq i \leq n\}$.

- **If d is an axiom**, the property trivially holds since $t' = u_i$ for some i which realizes $U_i = T$ by hypothesis.
- **If d ends with $\rightarrow I$** , one has $t = \lambda x.v$, $T = U \rightarrow V$, and $x_1 : U_1, \dots, x_n : U_n, x : U \vdash_{\mathbf{F}} v : V$. Let $v' = v \{u_i/x_i, 1 \leq i \leq n\}$. We want to prove that t' realizes T for valuation \mathbf{v} : one considers a stack $\pi \in \|T\|_{\mathbf{v}} \subseteq \Pi_0$.
There are only two possibilities: either no such stack exists and then t' realizes T trivially, or π has form $u \cdot \pi'$, with $u \Vdash_{\mathbf{v}} U$, $u \in \Lambda_0$ and $\pi' \in \|V\|_{\mathbf{v}}$, $\pi' \in \Lambda_0$.
In the second case, we know by induction hypothesis that $v' \{u/x\} \Vdash_{\mathbf{v}} V$ from which $(v' \{u/x\}, \pi') \in \perp$ and by closure by KAM-anti-reduction of \perp (more precisely by property 1.) and since $u \in \Lambda_0$, one also has that $(t \{u/x\}, u \cdot \pi') \in \perp$ which shows that $t' \Vdash_{\mathbf{v}} T$ since the stack was chosen arbitrarily.
- **If d ends with $\rightarrow E$** , then we have $t = (u)v$ with $x_1 : U_1, \dots, x_n : U_n \vdash_{\mathbf{F}} u : V \rightarrow T$ and $x_1 : U_1, \dots, x_n : U_n \vdash_{\mathbf{F}} v : V$ for some type V .

One can apply the induction hypothesis to both derivation d_u and d_v concluding $x_1 : U_1, \dots, x_n : U_n \vdash_F u : V \rightarrow T$ and $x_1 : U_1, \dots, x_n : U_n \vdash_F v : V$ which ensures that $u' = u \{u_i/x_i, 1 \leq i \leq n\}$ and $v' = v \{u_i/x_i, 1 \leq i \leq n\}$ realize respectively $V \rightarrow T$ and V for valuation \mathbf{v} .

To show that t' realizes T , it is enough to consider an arbitrary stack π in $\|T\|_{\mathbf{v}}$ and to remark that $v' \cdot \pi \in \|V \rightarrow T\|_{\mathbf{v}} \subseteq \Pi_0$ and thus that $(u', v' \cdot \pi) \in \perp$. As before one applies the closure properties of the pole: since $v' \in \Lambda_0$, the second closure property of the pole applies and one gets $(t', \pi) \in \perp$, which means, since π is any stack in $\|T\|_{\mathbf{v}}$, that $t' \Vdash_{\mathbf{v}} T$.

- **If d ends with $\forall I$** , then one has $T = \forall X.U$ and $x_1 : U_1, \dots, x_n : U_n \vdash_F t : U$ where X does not occur free in the U_i .

To show that $t' \Vdash_{\mathbf{v}} \forall X.U$, let us consider $\pi \in \|\forall X.U\|_{\mathbf{v}}$. We know by definition of the realizability interpretation that there exists $F \subseteq \Pi_0$ such that $\pi \in \|U\|_{\mathbf{v}[X:=F]}$.

But since X is not free in the U_i the interpretation of U_i is the same in \mathbf{v} and in $\mathbf{v}' = \mathbf{v}[X := F]$, in particular, the lemma hypothesis tells us that $u_i \Vdash_{\mathbf{v}'} U_i$ if $1 \leq i \leq n$. One can therefore apply the induction hypothesis to the subderivation of conclusion $x_1 : U_1, \dots, x_n : U_n \vdash_F t : U$ with respect to \mathbf{v}' : $t' \Vdash_{\mathbf{v}'} U$ so that $(t', \pi) \in \perp$ which proves that $t' \Vdash_{\mathbf{v}} \forall X.U$.

- **If d ends with $\forall E$** , then we have a subderivation d' of d , which concludes with $x_1 : U_1, \dots, x_n : U_n \vdash_F t : \forall X.U$, with $T = U \{V/X\}$ for some V .

Let us consider $\pi \in \|U \{V/X\}\|_{\mathbf{v}}$: we need to prove that $(t, \pi) \in \perp$. The substitutivity lemma ensures that $\pi \in \|U\|_{\mathbf{v}[X:=\|V\|_{\mathbf{v}}]}$.

By applying induction hypothesis to d' , we have $t' \Vdash_{\mathbf{v}} \forall X.U$ so for any $F \subseteq \Pi_0$, we have that $t' \Vdash_{\mathbf{v}[X:=F]} U$, and in particular when $F = \|V\|_{\mathbf{v}} \subseteq \Pi_0$.

We then deduce that $(t', \pi) \in \perp$.

This concludes the proof of the lemma. □

Adequation lemma allows to deduce easily that a typed term realizes its type and that typable terms are in the intersection of all admissible sets:

Theorem 3.5

If Λ_0 is admissible and $\Gamma \vdash_F t : T$, then $t \in \Lambda_0$.

Proof: Indeed, if Λ_0 is admissible, then there exists a pole \perp and a valuation \mathbf{v} adapted to Λ_0 . The adequation lemma can be applied to variables which are realizers of any type and $t = t \{x_i/x_i\} \in |T|_{\mathbf{v}} \subseteq \Lambda_0$. □

To prove strong normalization of F , it is therefore sufficient to prove that the set of strongly normalizing terms is admissible, that we will do in the following.

To be continued...
