LAMBDA CALCULUS

C.-H. L. Ong

© C.-H. L. Ong, 1997
Aim

Recursive functions are representable as lambda terms, and definability in the calculus may be regarded as a definition of computability. This forms part of the standard foundations of computer science. Lambda calculus is the commonly accepted basis of functional programming languages; and it is folklore that the calculus is the prototypical functional language in purified form. The course investigates the syntax and semantics of lambda calculus both as a theory of functions from a foundational point of view, and as a minimal programming language.

Synopsis

Formal theory, fixed point theorems, combinatory logic: combinatory completeness, translations between lambda calculus and combinatory logic; reduction: Church-Rosser theorem; Böhm’s theorem and applications; basic recursion theory; lambda calculi considered as programming languages; simple type theory and \( \text{pcf} \): correspondence between operational and denotational semantics; current developments.

Relationship with other courses

Basic knowledge of logic and computability in paper B1 is assumed.

1 Syntax of the \( \lambda \)-calculus

In this section we introduce the syntax of the untyped \( \lambda \)-calculus and fix some notations. Substitution is a key operation of the \( \lambda \)-calculus, which should be contrasted with context substitution. There are fixed-point operators in the \( \lambda \)-calculus – this has to do with the possibility of self-application in the untyped \( \lambda \)-calculus. The theories \( \lambda \beta \) and \( \lambda \beta \eta \) are introduced.

1.1 Basic definitions

The syntax of the \( \lambda \)-calculus is remarkably simple. \( \lambda \)-terms are defined by induction over the following rules:

- any variable is a \( \lambda \)-term
- if \( s \) and \( t \) are \( \lambda \)-terms then so is \( (s \cdot t) \) which is called an **application**
- if \( s \) is a \( \lambda \)-term then the \( \lambda \)-abstraction (or simply abstraction) \( (\lambda x.s) \) is a \( \lambda \)-term.

**Remark 1.1.1**  
(i) We use meta-variables \( s, s', s_1, t, t', \) etc. to range over \( \lambda \)-terms, and \( x, y, z, x_i, x' \) etc. to range over (denumerably many) variables. (Do not confuse the object-variables i.e. \( x, y, z \) etc. with meta-variables.)

(ii) The symbols \( (, ) \), \( \cdot \) are part of the language. They play an important rôle in disambiguating the structure of expressions. It is possible to minimize their use in a safe way. We write \( (s \cdot t) \) simply as \( st \) and \( (\lambda x.s) \) as \( \lambda x.s \), omitting \( \cdot \) and as many parentheses as we can get away with, subject to the following convention:

- abstraction associates to the right: \( \lambda x_1 \cdots x_n.s \) means \( \lambda x_1.(\lambda x_2.\cdots(\lambda x_n.s)\cdots) \).
- application associates to the left: \( s_1 \cdots s_n \) means \( (\cdots(s_1s_2)\cdots s_n) \).

(iii) \( \lambda x_1 \cdots x_n.s \) and \( s \) are shorthand for \( \lambda x_1 \cdots x_n.s \) and \( s_1 \cdots s_n \) respectively, for \( n \geq 0 \). So for example \( stu \) is a shorthand for \( st_1 \cdots t_n u \) for some \( n \geq 0 \).

1.2 Variables

An occurrence of a variable \( x \) in \( s \) is said to be **bound** if it is in the scope of some abstraction \( \lambda x.- \) in \( s \); otherwise \( x \) is **free** in \( s \). Formally we define the set \( \text{fv}(s) \) of free variables of \( s \) by recursion as follows:

\[
\text{fv}(x) \overset{\text{def}}{=} \{ x \}
\]

\[
\text{fv}(st) \overset{\text{def}}{=} \text{fv}(s) \cup \text{fv}(t)
\]

\[
\text{fv}(\lambda x.s) \overset{\text{def}}{=} \text{fv}(s) - \{ x \}.
\]

A term is said to be **closed** if every variable occurrence in it is bound. We write \( \Lambda \) for the set of \( \lambda \)-terms, and \( \Lambda^0 \) for the set of closed \( \lambda \)-terms.
1.3 Important convention

**α-convertibility** Two terms $s$ and $t$ are said to be α-convertible, written $s =_α t$, if one is obtainable from the other by renaming bound variables. E.g.,

$$\lambda x.y.x =_α \lambda z.y.z =_α \lambda z.x.z.$$  

We regard α-convertible terms as identical at the syntactic level; they are to all intents and purposes equal. We shall use $\equiv$ to mean syntactic equality; and reserve the more common symbol $=$ for β-convertibility. So $s =_α t$ implies $s \equiv t$.

**Variable convention** We state the convention informally as:

“We shall assume that there is an inexhaustible supply of fresh variable names so that given any (finite) number of λ-terms $s_1, \ldots, s_n$, bound variables occurring in them are renamed where necessary in such a way that none is the same as any variable occurring free in $s_1, \ldots, s_n$.”

1.4 β-conversion and substitution

What do λ-terms denote? λ-calculus is a theory of functions. Application is a binary operator. The λ-abstractor “$\lambda x.$$” in any abstraction $\lambda x.s$ can be thought of as a term-constructor of arity one. A term may act both as an operator (function) and as an operand (argument). E.g. $x$ in the term $xx$.

**β-conversion** Think of λ-terms as programs for the moment. What happens when a λ-term (an abstraction) is applied to another?

$$(\lambda x.s)t = s[t/x]$$

where $s[t/x]$ means “in $s$ substitute $t$ for every free occurrence of $x$”. **Substitution** is a very important operation in formal logic. In the λ-calculus

- substitution is an implicit operation i.e. the expression “$s[t/x]$” is not part of the object language; we are to understand “$s[t/x]$” as denoting the λ-term that is obtained from $s$ by substituting $t$ for every free occurrence of $x$ in $s$.

- substitution is an unrestricted operation; any term may be substituted for any variable. This is to be contrasted with the substitution mechanism of, say, the π-calculus of Milner, Parrow and Walker [MPW92], in which only names (as opposed to all π-terms) may participate in the operation.

Substitution may be defined by recursion as follows:

$$x[s/y] \overset{\text{def}}{=} \begin{cases} s & \text{if } x \equiv y \\ x & \text{otherwise} \end{cases}$$

$$(uv)[s/y] \overset{\text{def}}{=} (u[s/y]v[s/y])$$

$$(\lambda x.t)[s/y] \overset{\text{def}}{=} \lambda x.(t[s/y]).$$
Note that in the absence of the variable convention, the last clause should be replaced by

\[
(\lambda x. t)[s/y] \overset{\text{def}}{=} \begin{cases} 
\lambda x'.(t[x'/x][s/y]) & \text{if } x \equiv y \text{ or } x \in \text{fv}(s) \\
\lambda x.(t[s/y]) & \text{otherwise}
\end{cases}
\]

For example \((\lambda xy. zy)[yy/z] \) is \(\lambda xu.(yy)u\).

**Proposition 1.4.1 (Nested substitution)** For any variable \(x\) distinct from \(y\), if \(x\) does not occur free in \(u\),

\[
s[t/x][u/y] \equiv s[u/y][t[u/y]/x].
\]

**Proof** We prove by induction on the structure of \(s\). Consider the base case of \(s\) being a variable. If \(s \equiv x\) then both lhs and rhs are \(t[u/y]\). If \(s \equiv y\) then the lhs is \(u\); the rhs \(y[u/y][t[u/y]/x]\) is \(u[t[u/y]/x]\) which is \(u\) since \(x\) does not occur free in \(u\). For the remaining case of \(s\) being a variable distinct from \(x\) and \(y\), both sides give \(s\). Next suppose \(s \equiv s_1 s_2\).

\[
(s_1 s_2)[t/x][u/y] \equiv (s_1[t/x][u/y])(s_2[t/x][u/y]) \quad \text{by induction hypo.}
\]

\[
\equiv (s_1[u/y][t[u/y]/x])(s_2[u/y][t[u/y]/x])
\]

\[
\equiv (s_1[u/y] s_2[u/y])[t[u/y]/x]
\]

\[
\equiv (s_1 s_2)[u/y][t[u/y]/x].
\]

The case of \(s\) being an abstraction is left as an easy exercise. 

\[\square\]

### 1.5 Formal theories \(\lambda \beta\) and \(\lambda \beta \eta\)

[We shall assume knowledge of elementary logic; see for example Hamilton’s [Ham88] or Mendelson’s book [Men87].] A *theory* is a collection of formulae closed under a notion of provability or derivability. In this course terms are just the \(\lambda\)-terms and formulae are equations between terms, written \(s = t\).

**Proof system \(\lambda \beta\)**

There are three groups of axiom and rule *schema*.

1. **Equivalence**: these are the rules that define \(\equiv\) to be an equivalence relation

   \[
   \begin{align*}
   \text{(reflexivity)} & \quad s = s \\
   \text{(symmetry)} & \quad s = t \quad \quad t = s \\
   \text{(transitivity)} & \quad \frac{s = t \quad t = u}{s = u}
   \end{align*}
   \]

2. **Compatible closure**: these rules ensure that \(\equiv\) is a *congruence* i.e. \(\equiv\) is preserved by all contexts.
(application) \[
\begin{aligned}
  s & = s' \\
  t & = t' \\
  st & = st'
\end{aligned}
\]

(abstraction) \[
\begin{aligned}
  s & = t \\
  \lambda x.s & = \lambda x.t
\end{aligned}
\]

(3) \(\beta\)-conversion

\[
(\beta) \quad (\lambda x.s)t = [s[t/x]].
\]

The formal theory \(\lambda\beta\eta\) is \(\lambda\beta\) extended by the following axiom scheme

\[\lambda x.xs = s\quad \text{provided } x \text{ does not occur free in } s.\]

We write \(\lambda\beta \vdash s = t\) to mean that \(s = t\) is provable in the theory \(\lambda\beta\). Similarly for \(\lambda\beta\eta\).

**Notation** We shall often write \(\lambda\beta \vdash s = t\) simply as \(s = t\).

Here are some questions that we should ask about the theories:

(1) Is \(\lambda\beta\) (or \(\lambda\beta\eta\)) consistent? (A theory is said to be consistent if there is a formula which is not a theorem. Warning: consistency has several subtly different meanings in logic.)

(2) Is \(\lambda\beta\) (or \(\lambda\beta\eta\)) maximally consistent (i.e. for any \(s\) and \(t\), either \(\lambda\beta \vdash s = t\), or \(\lambda\beta + (s = t)\) - the theory obtained by augmenting \(\lambda\beta\) by the equation \((s = t)\) - is inconsistent)?

(3) Is equality = in \(\lambda\beta\) (or in \(\lambda\beta\eta\)) decidable?

### 1.6 Fixed points

For \(\lambda\)-terms \(f\) and \(u, u\) is said to be a **fixed point** of \(f\) if \(fu = u\). A **fixed-point combinator** is a (closed) term \(f\) such that \(s(fs) = fs\) for all \(\lambda\)-term \(s\). (A combinator is just a closed \(\lambda\)-term, for which more anon.) In the \(\lambda\)-calculus, the so-called first recursion theorem is (almost) a triviality.

**Proposition 1.6.1 (First Recursion Theorem)** There are (many) fixed-point combinators in the \(\lambda\)-calculus.

Here are two well-known ones:

- Curry’s “paradoxical” combinator: \(y \overset{\text{def}}{=} \lambda f.(\lambda x.f(xx))(\lambda x.f(xx))\)

- Turing’s fixed-point combinator: \(\Theta \overset{\text{def}}{=} AA\) where \(A\) is defined to be \(\lambda xy.y(xx)\).

For example \(yg = (\lambda x.g(xx))(\lambda x.g(xx)) = g((\lambda x.g(xx))(\lambda x.g(xx))) = g(yg)\).

### 1.7 Contexts

Intuitively these are \(\lambda\)-terms that contain “holes”. We use meta-variables \(X, X', Y, Y'\) etc. to denote such “holes” – call them **hole-variables**. **Examples of context**: \(\lambda x.Xx\) (or more suggestively \(\lambda x.[/][x]\)), \(X(zyX(\lambda x.Y))\). Contexts are ranged over by \(C, C', D\) etc.
Definition 1.7.1 Contexts (or \(\lambda\)-contexts) are defined by the following BNF rule:

\[
C ::= x \mid X \mid (CC) \mid (\lambda x.C).
\]

As usual we adopt the convention of leaving out as many parentheses as we can get away with. We often write a context \(C\) in a more informative way as \(C[X_1, \ldots, X_n]\) whenever the hole-variables occurring in \(C\) belong to the set \(\{X_1, \ldots, X_n\}\).

Context substitution

It is important to distinguish context substitution from variable substitution: in the former, variable capture may happen i.e. variables may become bound as a result of the operation; but not in the latter. For example take \(C[X]\) to be \(\lambda x.Xyx\). Then \(C[x]\) is \(\lambda x.xyz - x\) is bound or “captured” as a result; contrast this with \((\lambda x.\, zyx)[x/z]\), which is \(\lambda u.\, zyu\).

Formally we define \(C[s_1, \ldots, s_n]\), the context-substitution of \(\lambda\)-terms \(s_1, \ldots, s_n\) for hole-variables \(X_1, \ldots, X_n\) in \(C \equiv C[X_1, \ldots, X_n]\), as follows: (we shall write \(C[s]\) as a short hand for \(C[s_1, \ldots, s_n]\))

\[
C[s_1, \ldots, s_n] \equiv \begin{cases} 
C & \text{if } C \text{ is a term variable} \\
 s_i & \text{if } C = X_i \\
 C_1[s]C_2[s] & \text{if } C \equiv C_1C_2 \\
 \lambda x.\, C'[s] & \text{if } C \equiv \lambda x.\, C'.
\end{cases}
\]

Context is an important tool for reasoning about properties of syntax.

Problems

Problems contained in this exercise (and in future installments) supplement the lectures. Students are advised to work through them. Problems marked with ★ may be difficult.

1.1 (i) Rewrite \(((xy)(\lambda y(\lambda z.(z(xy))))))\) using the minimum number of parentheses

(ii) Fill in all possible parentheses in \((\lambda xyz.\, x(yz))\lambda xy, x)\).

1.2 Perform the following substitutions:

(i) \((\lambda x.\, yx)[yz/x]\)

(ii) \((\lambda y.\, xy)[yx/x]\)

(iii) \((\lambda z.\, (\lambda x.\, xz)xz)[zx/x]\)

(iv) \(C[yz]\) where \(C[X] \equiv \lambda z.\, (\lambda x.\, yx)Xz\)

(v) \(C[yx]\) where \(C[X] \equiv \lambda y.\, Xy\).
1.3 A **proof** of the formal system $\lambda\beta$ is a finite sequence $l$ of formulae (=equations) such that every formula $\theta$ of $l$ is either an instance of an axiom, or it is the conclusion of an instance of a rule whose corresponding instances of the premises occur to the left of $\theta$ in $l$.

Write down a proof of $(\lambda x.(\lambda z. z)(((\lambda y.y)x)u) = (\lambda x.xx)u$, and construct its **proof tree**.

1.4 Prove the following:

(i) if $s = t$ then $s[u/x] = t[u/x]$ for any $u$

(ii) if $s = t$ then $u[s/x] = u[t/x]$ for any $u$

(iii) if $s = t$ and $p = q$ then $s[p/x] = t[q/x]$.

1.5 Prove that if $s = t$ then for any context $C[-]$, $C[s] = C[t]$.

1.6 Show that there exists $s$ such that $st = ss$ for all $t$.

1.7 Show that there is no $\lambda$-term $f$ satisfying the following property:

for any $\lambda$-terms $s$ and $t$, $f(st) = s$.

[Hint: use the Fixed Point Theorem.]

1.8 Use the Fixed-Point Theorem to construct:

1. a closed $\lambda$-term $t$ such that $t = ts$ where $s$ is the standard $S$-combinator.

2. a closed $\lambda$-term $M$ such that $M^s = Ms$ where $i$ is the standard identity combinator.

1.9 ★ Show that every fixed-point combinator can be characterized as a fixed point of a term $G$. Find $G$.

1.10 ★ Show that there are denumerably many ($\beta$-inequivalent) fixed-point combinators. Generate these combinators by a “uniform” procedure.

1.11 It is known that the $\eta$-axiom is not derivable from the formal system $\lambda\beta$. († Can you show it?) However for any $s$ which is $\beta$-equivalent to a $\lambda$-abstraction, $\lambda x. sx = s$, for $x$ not occurring free in $s$. Why is this so?
2 Reduction

Using $\beta$-reduction as the main example, we introduce the basic notions of term rewriting such as weak and strong normalization, and Church-Rosser. $\beta$-reduction is shown to be Church-Rosser.

2.1 Preliminaries: rule induction

For an introduction to rule induction see e.g., the treatment in chapter 4 of Winskel’s book [Win93] (especially the Principle of Rule Induction); for a more foundational approach, see Aczel’s chapter in the Handbook of Mathematical Logic [Bar77].

Subterm of a $\lambda$-term is defined by induction as follows:

- a $\lambda$-term is a subterm of itself
- if $u$ is a subterm of $s$ then it is a subterm of $\lambda x.s$
- if $u$ is a subterm of $s$ the it is a subterm of both $st$ and $ts$.

Let $T$ be a set of terms. Typically $T$ is defined by induction over a set of formation rules. The formation rule $R_c$ defining a constructor $c$ of $T$ has the general form:

$$R_c : \frac{s_1 \in T \ldots s_n \in T}{c(s_1, \ldots, s_n) \in T}$$

where $c$ is a term constructor. For example the collection $\Lambda$ of $\lambda$-terms can be defined by induction over the following formation rule schema:

$$x \in \Lambda \quad s \in \Lambda \quad t \in \Lambda \quad s \in \Lambda$$

$$\frac{s \cdot t \in \Lambda}{(s \cdot t) \in \Lambda} \quad \frac{\lambda x.s \in \Lambda}{(\lambda x.s) \in \Lambda}$$

2.2 Some basic notions of term rewriting

Term rewriting is a subject in theoretical computer science in its own right: for a survey, see the respective chapters in the MTP Press Handbook of Theoretical Computer Science [vL90] and the OUP Handbook of Logic in Computer Science [AGM93]. We shall not study term rewriting in general in this section but rather regard $\lambda$-calculus as a particular term rewriting system.

A redex rule (or notion of reduction) $R$ over $T$ is just a binary relation $R$ over $T$ (of a certain kind). Take $T$ to be the set of $\lambda$-terms, and $R$ the redex rule

$$\beta = \{ ((\lambda x.s)t, s[t/x]) : s \text{ and } t \text{ are } \lambda\text{-terms, } x \text{ a variable} \}.$$  

We define the corresponding one-step $\beta$-reduction by induction over the following rule schema:

$$s \rightarrow t \quad \frac{s \rightarrow s'}{st \rightarrow st'} \quad \frac{t \rightarrow t'}{st \rightarrow st'} \quad \frac{s \rightarrow s'}{\lambda x.s \rightarrow \lambda x.s'}$$

The first rule scheme is only applied whenever the predicate on the r.h.s., known as the side condition, is satisfied.

Though $\beta$ is the main redex rule we shall study in this course, the idea of one-step reduction is quite general. Given an arbitrary redex rule or notion of reduction $R$ over a set $T$ of terms, we define the corresponding one-step reduction, which we call one-step $R$-reduction, as follows.
**Definition 2.2.1** (Informal) A binary relation $R$ over $\mathcal{T}$ is said to be closed under the formation rule $R_c$ (as above) argumentwise just in case for any $s_1, \ldots, s_n$, and for each $i$, if $s_i R s_i'$ then
\[ c(s_1, \ldots, s_i, \ldots, s_n) R c(s_1, \ldots, s_i', \ldots, s_n). \]
The **compatible closure** of the redex rule $R$, or **one-step $R$-reduction**, is defined to be the least (w.r.t. inclusion) binary relation containing $R$ and closed under all the formation rules argumentwise.

**Notation** Let $R$ be a redex rule or notion of reduction over $\mathcal{T}$.
\[
\begin{align*}
\rightarrow_R & \overset{\text{def}}{=} \text{compatible closure of } R \text{ or one-step } R\text{-reduction} \\
\rightarrow_R^- & \overset{\text{def}}{=} \text{reflexive, transitive closure of } \rightarrow_R \\
\rightarrow_R^+ & \overset{\text{def}}{=} \text{transitive closure of } \rightarrow_R \\
=_{R} & \overset{\text{def}}{=} \text{reflexive, symmetric, transitive closure of } \rightarrow_R.
\end{align*}
\]
We shall be a little vague about what exactly is a redex rule or notion of reduction. Intuitively a notion of reduction is a binary relation from which we derive the corresponding one-step reduction (by taking compatible closure).

**Proposition 2.2.2** For $\lambda$-terms $s$ and $t$, $\lambda \beta \vdash s = t$ if and only if $s =_{\beta} t$. \qed

The following are obvious:

- $s \rightarrow_R t$ if and only if for some $n \geq 0$ and for some $s_1, \ldots, s_n$,
  \[ s \equiv s_0 \rightarrow_R s_1 \rightarrow_R \cdots \rightarrow_R s_n \equiv t; \]

- $s \rightarrow_R^+ t$ if and only if for some $n \geq 1$ and for some $s_1, \ldots, s_n$,
  \[ s \equiv s_0 \rightarrow_R s_1 \rightarrow_R \cdots \rightarrow_R s_n \equiv t. \]

Intuitively an $R$-redex is the “smallest” syntactic unit that contributes to (an instance of) one-step reduction. A $\beta$-redex is a $\lambda$-term that has the general shape $(\lambda x. s)t$, i.e., the shape of the lhs of the redex rule $\beta$.

**Remark 2.2.3** Let $R$ be a redex rule over $\mathcal{T}$. The following is generally valid:
\[
s \rightarrow_R s' \iff \left\{ \begin{array}{l}
\text{for some "one-holed" } \mathcal{T}\text{-context } C[X] \text{ and} \\
\text{for some } R\text{-redex } \Delta, C[\Delta] \equiv s \text{ and } s' \equiv C[\Delta'] \text{ and } \Delta \ R \Delta'.
\end{array} \right.
\]
A one-holed context is one in which the hole occurs exactly once.

### 2.3 Some desirable properties of term rewriting systems

(For the rest of this section, we shall assume that $R$ is a redex rule over $\mathcal{T}$.)

A term $s$ of $\mathcal{T}$ is said to be an $R$-normal form ($R$-NF or simply normal form if $R$ is clear from the context) provided there is no $t$ for which $s \rightarrow_R t$. By definition of $\rightarrow_R$, a term $s$ is an $R$-NF if and only if no subterm of $s$ is an $R$-redex. A term $s$ has an $R$-normal form just in case $s$ reduces to an $R$-normal form i.e. $s \rightarrow_R s_1 \rightarrow_R s_2 \rightarrow_R \cdots \rightarrow_R s_n$ and $s_n$ is an $R$-normal form, for some terms $s_1, \ldots, s_n$. 
Example 2.3.1 (i) $\Delta_n \equiv \lambda x_1 x_2 \cdots x_n \ s \equiv \lambda xy_1 x_2 (y_2), \ k \equiv \lambda xy. x$ are in $\beta$-NF.

(ii) $\Omega \equiv (\lambda x. xx)(\lambda x. xx), \ \Delta_m \Delta_n$ for $m, n \geq 2$, $yi$ and $yk$ do not have any $\beta$-NF, where $y$ is any fixed-point combinator.

Definition 2.3.2 (i) A term $s$ is said to be normalizable (w.r.t. a one-step reduction $\rightarrow R$) if $s$ has an $R$-normal form.

(ii) A term $s$ is said to be strongly normalizable (w.r.t. $\rightarrow R$) if there is no infinite one-step reduction emanating from $s$; equivalently every one-step reduction sequence emanating from $s$ terminates at an $R$-normal form after finitely many steps.

(iii) The one-step reduction $\rightarrow R$ is weakly normalizing if there is a reduction strategy that reduces every term to its $R$-normal form. A reduction strategy is a map that associates to each non-normal term a subterm that is a redex. A reduction strategy that reduces every term to its $R$-normal form if it has one is called normalizing.

(iv) The one-step reduction $\rightarrow R$ is strongly normalizing if every term $s$ is strongly normalizable w.r.t. $\rightarrow R$; equivalently there is no infinite one-step $R$-reduction sequence.

Clearly if $s$ is strongly normalizable then it is weakly normalizable. Hence if a one-step reduction is strongly normalizing then it is weakly normalizing. In untyped $\lambda$-calculus $\beta$-reduction is neither weakly nor strongly normalizing. However $\beta$-reduction in simply-typed $\lambda$-calculus and second-order polymorphic $\lambda$-calculus (or System F) is strongly normalizing.

Let $R$ be a redex rule over $T$. We say that $\rightarrow_R$ satisfies

(i) **diamond property** if $s \rightarrow_R t_1$ and $s \rightarrow_R t_2$ implies $t_1 \rightarrow_R t$ and $t_2 \rightarrow_R t$ for some $t$.

(ii) **Church-Rosser property** if $s \rightarrow_R t_1$ and $s \rightarrow_R t_2$ implies $t_1 \rightarrow_R t$ and $t_2 \rightarrow_R t$ for some $t$; equivalently if $\rightarrow_R$ satisfies the diamond property.

How are the two properties related?

**Lemma 2.3.3** Let $R_0$ be a binary relation. If $R_0$ satisfies the diamond property then the transitive closure of $R_0$ satisfies the diamond property.

**Proof** By a “diagram chase”.

We say that a redex rule $R$ (over $T$), or $\rightarrow R$, has **unique normal form property** if whenever a term has normal forms they are equal.

### 2.4 Church-Rosser property of $\beta$-reduction

The rest of the section is devoted to a proof of the following result:

**Theorem 2.4.1** The one-step $\beta$-reduction is Church-Rosser.

We shall prove this theorem by a method of “parallel reduction” due to P. Martin-Löf and W. W. Tait. Define a notion of parallel $\beta$-reduction as a binary relation $\gg$ over $\lambda$-terms by induction over the following rules:
Our strategy shall be to prove

1. \( \gg \) satisfies the diamond property, and
2. \( \rightarrow_{\beta} \) is the transitive closure of \( \gg \).

Hence by Lemma 2.3.3 \( \rightarrow_{\beta} \) satisfies the diamond property. To establish (1) we first prove:

**Lemma 2.4.2 (Substitution)** If \( s \gg s' \) and \( t \gg t' \) then \( s[t/x] \gg s'[t'/x] \).

**Proof** We prove by induction over the structure of \( s \) and by case analysis of the definition of \( s \gg s' \) by rule induction.

- **(refl)** Suppose \( s \equiv s' \).

<table>
<thead>
<tr>
<th>( s )</th>
<th>( s[t/x] )</th>
<th>( s'[t'/x] \equiv s'[t'/x] )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x )</td>
<td>( t )</td>
<td>( t' )</td>
</tr>
<tr>
<td>( y )</td>
<td>( y )</td>
<td>( y )</td>
</tr>
<tr>
<td>( pq )</td>
<td>( p[t/x]q[t/x] )</td>
<td>( p[t'/x]q[t'/x] )</td>
</tr>
<tr>
<td>( \lambda y.p )</td>
<td>( \lambda y.(p[t/x]) )</td>
<td>( \lambda y.(p[t'/x]) )</td>
</tr>
</tbody>
</table>

- **(app)** Write \( s \equiv s_1s_2 \), \( s' \equiv s'_1s'_2 \). By supposition \( s_1 \gg s'_1 \) and \( s_2 \gg s'_2 \). Since \( s_1 \) and \( s_2 \) are smaller than \( s \), by the induction hypothesis, \( s_1[t/x] \gg s'_1[t'/x] \) and \( s_2[t/x] \gg s'_2[t'/x] \). Hence the result follows from (app).

- **(abs)** Exercise.

- **(\( \triangledown \beta \))** Suppose \( s \equiv (\lambda y.p)q \) and \( s' \equiv p'[q'/y] \) with \( p \gg p' \) and \( q \gg q' \). By the induction hypothesis, \( p[t/x] \gg p'[t'/x] \) and \( q[t/x] \gg q'[t'/x] \). Thus

\[
(\lambda y.p)q[t/x] \equiv (\lambda y.p[t/x])(q[t/x])
\]

\[
\gg p'[t'/x][q'[t'/x]/y] \quad \text{by (\( \triangledown \beta \))}
\]

\[
= (p'[q'/y])[t'/x]. \quad \text{by Prop. 1.4.1 (Nested substitution)}
\]
Observe that by definition of $\gg$ we have

(i) If $\lambda x.s \gg t$ then $t$ has the shape $\lambda x.s'$ and $s \gg s'$

(ii) If $st \gg u$ then

- either $u$ has the shape $s't'$ and $s \gg s'$ and $t \gg t'$
- or $s$ has the shape $\lambda x.p$ and $u \equiv p[t'/x]$ with $p \gg p'$ and $t \gg t'$.

**Proposition 2.4.3** $\gg$ satisfies the diamond property.

**Proof** Suppose $s \gg s_1$ and $s \gg s_2$. We show by structural induction and by case analysis of the definition of $s \gg s_1$ that $s_1 \gg t$ and $s_2 \gg t$, for some $t$.

- (refl) By assumption $s \gg s \equiv s_1$. Take $t$ to be $s_2$.

- (app) By assumption $s \equiv pq$, $s_1 \equiv p_1q_1$ with $p \gg p_1$ and $q \gg q_1$. By the preceding observation we consider two subcases:

  - $s_2 \equiv p_2q_2$ with $p \gg p_2$ and $q \gg q_2$. By the induction hypothesis $p_1 \gg p$ and $p_2 \gg p$, $q_1 \gg q$ and $q_2 \gg q$ for some $p$ and $q$. Hence the result follows by taking $t$ to be $pq$ and by (app).

  - $p \equiv \lambda x.u$ and $s_2 \equiv u_2[q_2/x]$ with $u \gg u_2$ and $q \gg q_2$. Suppose $p_1 \equiv \lambda x.u_1$ with $u \gg u_1$. By the induction hypothesis we have, for some $u_1 \gg u_1$ and $u_2 \gg u_2$; and for some $q$, $q_1 \gg q$ and $q_2 \gg q$. Hence by ($[\beta]$), ($\lambda x.u_1)q_1 \gg u[q/x]$ and, by the Substitution Lemma 2.4.2, $u_2[q_2/x] \gg u[q/x]$.

- (abs) Exercise.

- ($[\beta]$) By assumption $s \equiv (\lambda x.p)q$ and $s_1 \equiv p_1[q_1/x]$ with $p \gg p_1$ and $q \gg q_1$. By the previous observation there are two cases:

  - $s_2 \equiv (\lambda x.p_2)q_2$ with $p \gg p_2$ and $q \gg q_2$. By the induction hypothesis, for some $p$, $p_1$ and $p_2 \gg p$, and for some $q$, $q_1$ and $q_2 \gg q$. Hence, by the Substitution Lemma, $p_1[q_1/x] \gg p[q/x]$, and by ($[\beta]$), $(\lambda x.p_2)q_2 \gg p[q/x]$.

  - $s_2 \equiv p_2[q_2/x]$ with $p \gg p_2$ and $q \gg q_2$, same as before.

Finally we check that

**Lemma 2.4.4** $\equiv_\beta$ is the transitive closure of $\gg$.

**Proof** It suffices to show that

"reflexive closure of $\equiv_\beta$" $\subseteq \gg \subseteq \equiv_\beta$.

The first inclusion is obvious; the second is easily verified by induction over the rules that define $\gg$. □

Hence we see that $\beta$ is Church-Rosser.
Other forms of reduction in \(\lambda\)-calculus

\(\eta\)-\textit{reduction} and \(\eta\)-\textit{expansion} over untyped \(\lambda\)-terms are the respective compatible closures of the following notions of reduction:

\[
\eta^{\text{red}} \overset{\text{def}}{=} \{ \langle \lambda x. sx, s \rangle : x \text{ is not free in } s \} \\
\eta^{\text{exp}} \overset{\text{def}}{=} \{ \langle s, \lambda x. sx \rangle : x \text{ is not free in } s \}.
\]

The notion of reduction \(\beta\eta\) is the union of \(\beta\) and \(\eta^{\text{red}}\).

**Proposition 2.4.5** The one-step \(\beta\eta\)-reduction is Church-Rosser.

A proof can be found e.g. in [Bar84, p. 66].

### 2.5 Why is the Church-Rosser property important?

Church-Rosser property is a standard test for consistency of an equational theory in a sense which we shall make clear shortly. Let \(E\) be a formal theory of equations over terms of \(T\). We say that a notion of reduction \(R\) \textit{implements} \(E\) just when the equivalence relation \(\sim_R\) induced by \(R\) coincides with \(E\).

**Proposition 2.5.1** Suppose \(R\) implements \(E\). If \(R\) is Church-Rosser and if there are distinct \(R\)\-normal forms then \(E\) is consistent (i.e. there are distinct terms \(s\) and \(t\) that are not provably equal in \(E\)).

**Proof** Note that by definition \(s \sim_R t\) if and only if

\[
s \xrightarrow{s_1} t_1 \xrightarrow{t_{n-1}} \ldots \xrightarrow{s_n} t_n \equiv t
\]

for some \(s_1, t_1, \ldots, s_n, t_n\). We claim: if \(R\) is Church-Rosser then \(s \sim_R t\) if and only if for some \(u\), both \(s \xrightarrow{\sim_R} u\) and \(t \xrightarrow{\sim_R} u\).

Now take \(s\) and \(t\) to be two distinct \(R\)\-normal forms. Suppose \(R\) is Church-Rosser. For a contradiction, suppose \(s \equiv t\) is provable in \(E\). Hence by \(R\)-implementability, \(s \sim_R t\), which implies, by the claim, that both \(s \xrightarrow{\sim_R} u\) and \(t \xrightarrow{\sim_R} u\), for some \(u\) — a contradiction.

**Corollary 2.5.2** Since there are distinct \(\beta\)-normal forms, and \(\beta\) is Church-Rosser, \(\lambda\beta\) is consistent.

**Proposition 2.5.3** Suppose \(R\) implements \(E\). If \(\rightarrow_R\) is both weakly normalizing and Church-Rosser then \(E\) is decidable.

**Proof** Take any terms \(s\) and \(t\). Weak normalization gives a strategy that reduces \(s\) and \(t\) to normal form in finitely many steps. Since \(R\) implements \(E\), \(s \equiv t\) in \(E\) if and only if they have the same normal form. It then remains to appeal to Church’s Thesis.
2.5 Why is the Church-Rosser property important?

Problems

2.1 List all the subterms of \( \lambda f.(\lambda x.f(xx))(\lambda x.f(xx)) \).

2.2 Give pairs of \( \lambda \)-terms to show that the following inclusions are strict:
\[
\rightarrow_\beta \subseteq \rightarrow^+_\beta \subseteq \rightarrow_\eta \subseteq =_\beta .
\]

2.3 Show that Remark 2.2.3 is true in the case of \( \beta \)-reduction over \( \lambda \)-terms.

2.4 Show that the following \( \lambda \)-terms have a \( \beta \)-normal form: set \( s \equiv \lambda xyz.x(zy) \)

(i) \((\lambda yz.zy)((\lambda x.xxx)(\lambda x.xxx))(\lambda wx.x)\)
(ii) \((\lambda y.yyy)((\lambda ab.a)(\lambda x.x)(ss))\)

2.5 Prove the following:

(i) If \( \rightarrow_R \) is Church-Rosser then it has unique normal form property, but not vice versa.

(ii) If \( \rightarrow_R \) is strongly normalizing and has unique normal form property then it is Church-Rosser.

Is the statement still valid if \( \rightarrow_R \) is only weakly normalizing?

2.6 Consider \( \beta \)-reduction. Give three \( \lambda \)-terms that are:

(i) in \( \beta \)-normal form
(ii) not in \( \beta \)-normal form but strongly normalizable
(iii) normalizable but not strongly normalizable
(iv) non-normalizable.

2.7 Prove the Substitution Lemma for \( \beta \)-reduction: for any terms \( s, t \) and \( u \), and for any variable \( x \), if \( s \rightarrow_\beta t \) then \( s[u/x] \rightarrow_\beta t[u/x] \).

2.8 Define by recursion the collection of \( \beta \)-normal forms. Describe the collection of \( \beta \eta \)-normal forms.

2.9 Write out the argument for the case of (abs) in Lemma 2.4.2 and the same in Lemma 2.4.3.

2.10 Prove that the notion of reduction \( \beta \) implements the proof system \( \lambda \beta \). That is to say, for any \( \lambda \)-terms \( s \) and \( t \), \( \lambda \beta \vdash s = t \) if and only if \( s =_\beta t \) (the latter is defined w.r.t. the notion of reduction \( \beta \)).

2.11 We say that \( \lambda \)-terms \( s \) and \( t \) are incompatible just in case the formal theory obtained by augmenting \( \lambda \beta \) with \( s = t \) is inconsistent. Prove by contradiction that (the usual combinators considered as \( \lambda \)-terms) \( s \) and \( k \) are incompatible. [Hint: By applying both sides of the equation \( s = k \) to appropriate \( \lambda \)-terms \( p, q \) and \( r \), show that \( i = s \) for all \( s \).]

Show further that
(i) $i$ and $k$ are incompatible

(ii) $i$ and $s$ are incompatible

(iii) $xy$ and $yx$ are incompatible.

[We shall see later in the course by Böhm’s Theorem that any $\lambda$-theory that equates any two $\beta\eta$-inequivalent normal forms is inconsistent.]

**2.12** Let $\rightarrow_1$ and $\rightarrow_2$ be two binary relations on a set $T$. Say that $\rightarrow_1$ and $\rightarrow_2$ *commute* just in case whenever $s \rightarrow_1 t_1$ and $s \rightarrow_2 t_2$ then there is some $t$ such that $t_1 \rightarrow_2 t$ and $t_2 \rightarrow_1 t$.

A lemma of Hindley and Rosen states that if $\rightarrow_1$ and $\rightarrow_2$ both satisfy the diamond property and commute with each other then the reflexive transitive closure of $(\rightarrow_1 \cup \rightarrow_2)$ satisfies the diamond property.

Prove the lemma. Hence show that if $\rightarrow_1$ and $\rightarrow_2$ are Church-Rosser and $\rightarrow_1$ commutes with $\rightarrow_2$ then $(\rightarrow_1 \cup \rightarrow_2)$ is Church-Rosser.

**2.13** By using the preceding lemma of Hindley and Rosen, prove that the notion of reduction $\lambda\beta\eta^{\text{red}}$ is Church-Rosser.

**2.14** Add to $\Lambda$ (the collection of $\lambda$-terms) constants $\delta$ and $\epsilon$. Define on the extended terms the following notion of reduction $\delta$:

\[ \delta ss \rightarrow \epsilon. \]

Show that $\lambda\beta\delta$ is not Church-Rosser.
3 Combinatory logic

The section gives a brief introduction to the theory of combinatory logic. Models of combinatory logic are called combinatory algebras which may be characterized as applicative structures that satisfy the axiom of combinatory completeness. Various extensionality axioms are introduced. A major theme is the translation between combinatory logic and the \( \lambda \)-calculus, and the nature of their relationship as theories.

This section assumes basic knowledge of first-order predicate logic; see e.g. the relevant chapters of [Ham88] or [Men87].

3.1 Combinatory algebra

We shall consider theories in first-order predicate calculus with equality.

**Notation** Fix such a language \( \mathcal{L}_0 \) that has a binary function symbol \( \cdot \). For terms \( a, b \) of \( \mathcal{L}_0 \), we write \( a \cdot b \) simply as \( ab \), and for any variable \( x \) of \( \mathcal{L}_0 \), \( a[b/x] \) shall mean the term obtained from \( a \) by substituting \( b \) for every occurrence of \( x \). We shall assume the same notational convention for application as before i.e. \( abcd \) means \( ((ab)c)d \) etc. A model for \( \mathcal{L}_0 \) is called an applicative structure.

**Definition 3.1.1** Let \( \mathcal{L} \) be the language obtained by adding constant symbols \( k, s \) to \( \mathcal{L}_0 \). Consider the axioms

\[
(C_0) \quad \begin{cases} 
  kxy = x \\
  sxyz = xz(yz).
\end{cases}
\]

Note that it is the same as considering the closure of \( (C_0) \), i.e.,

\[
\begin{cases} 
  \forall xy. kxy = x \\
  \forall xyz. sxyz = xz(yz).
\end{cases}
\]

A model of this system of axioms is called a (total) combinatory algebra.

We shall use the following notations:

- \( M \models F \) means the formula \( F \) is satisfied in the model \( M \) of \( \mathcal{L} \)
- \( S \vdash F \) means the closed formula \( F \) is a consequence of the set \( S \) of formulae.

3.2 Abstraction algorithm

Define an operation \( \mathcal{L} \rightarrow \mathcal{L} \) parametrized by variables \( x \) of \( \mathcal{L} \): for each \( x \), there is a map \( a \mapsto \lambda x.a \), where \( a \in \mathcal{L} \) and where \( \lambda x.a \) is defined by recursion as:

\[
\begin{align*}
\lambda x.x &\overset{\text{def}}{=} \text{skk} \\
\lambda x.a &\overset{\text{def}}{=} ka \quad \text{if } x \text{ does not occur free in } a \\
\lambda x.ab &\overset{\text{def}}{=} s(\lambda x.a)(\lambda x.b).
\end{align*}
\]

Note that \( \lambda x.(\cdot) \) maps \( \mathcal{L} \) to \( \mathcal{L} \) – not to be confused with \( \lambda \)-abstraction. We shall often use \( i \) as a shorthand for \( \text{skk} \). Nested abstractions \( \lambda x_1.(\cdots \lambda x_n.(-)) \) shall be written as \( \lambda x_1 \cdots x_n.(-) \).
Proposition 3.2.1 (\(\beta\)-simulation) For each \(a \in \mathcal{L}\),

(i) \(x\) does not occur free in \(\lambda x.a\), and

(ii) \(C_0 \vdash \forall x.((\lambda x.a)x = a)\).

(iii) Hence it follows that \(C_0 \vdash (\lambda x.a)b = a[b/x]\) for all \(b \in \mathcal{L}\).

(iv) (ii) extends to

\[ C_0 \vdash \forall x_1 \cdot \cdot \cdot x_n,((\lambda x_1 \cdot \cdot \cdot x_n.a)x_1 \cdot \cdot \cdot x_n = a) \]

with \(\text{fv}(a) \subseteq \{x_1, \cdot \cdot \cdot, x_n\}\).

\textbf{Proof} \ (i) can be proved easily by an induction on the size of \(a\). (ii) is proved by structural induction on \(a\). Suppose \(D \vdash C_0\). Fix \(a \in \mathcal{L}\). Take any \(d \in D\). We write \([t]_\rho\) for the interpretation of \(t\) in \(D\) given the variable valuation \(\rho\). Now take \(\rho\) to be a valuation that maps \(x\) to \(d\). We aim to prove \([([\lambda x.a])_\rho]d = [a]_\rho\). Suppose \(a = x\). Then \(l.h.s. = [i]_\rho d = d = r.h.s.\) Suppose \(x \notin a\). Then \(l.h.s. = [([\lambda x.a])_\rho]d = [[\lambda a]_\rho d = [a]_\rho = r.h.s.\) Finally suppose \(a = a_1 a_2\).

\[ [\lambda x.a_1 a_2]_\rho d = [[s(\lambda x.a_1)(\lambda x.a_2)]_\rho d \]

\[ = [[\lambda x.a_1]_\rho d[[\lambda x.a_2]_\rho d \quad \text{by the induction hypothesis} \]

\[ = [a_1]_\rho [a_2]_\rho = [a_1 a_2]_\rho.\]

(iii) is an immediate consequence of (ii). We prove (iv) by induction on \(n\). The base case is (ii). For the inductive case of \(n = r + 1\), note that by (i) variables occurring free in \(\lambda x_2 \cdot \cdot \cdot x_{r+1}.a\) are contained in \(\{x_1\}\). Hence by (ii) \(C_0 \vdash (\lambda x_1. (\lambda x_2 \cdot \cdot \cdot x_{r+1}.a))x_1 = \lambda x_2 \cdot \cdot \cdot x_{r+1}.a;\) and so

\[ C_0 \vdash (\lambda x_1. (\lambda x_2 \cdot \cdot \cdot x_{r+1}.a))x_1 x_2 \cdot \cdot \cdot x_{r+1} = (\lambda x_2 \cdot \cdot \cdot x_{r+1}.a)x_2 \cdot \cdot \cdot x_{r+1}.\]

Hence by the induction hypothesis \(C_0 \vdash (\lambda x_1 \cdot \cdot \cdot x_{r+1}.a)x_1 \cdot \cdot \cdot x_{r+1} = a.\)

\(\square\)

Proposition 3.2.2 All non-trivial combinatory algebras are infinite.

\textbf{Proof} \ Fix \(n\). Suppose there is a combinatory algebra \(A\) of size \(n\). For each natural number \(i\) where \(1 \leq i \leq n + 1\), define \(a_i\) to be \(\lambda x_1 \cdot \cdot \cdot x_{i-1}.x_i\). Then, w.l.o.g., say, \(A \vdash a_1 = a_2\). So for any distinct \(b_1\) and \(b_2\) of \(A\), we have \([a_1]b_1 b_2 \cdot \cdot \cdot b_2 = [a_2]b_1 b_2 \cdot \cdot \cdot b_2\), and so \(b_1 = b_2 - a\) contradiction. \(\square\)

3.3 Combinatory completeness

An applicative structure \(A\) is said to be \textbf{combinatory complete} if for every term \(t\) of \(\mathcal{L}_0\) with all free variables of \(t\) occurring in \(\{x_1, \cdot \cdot \cdot, x_n\}\) and constant parameters from \(A\), there is an element \(f\) in \(A\) such that

\[ (cc) \quad A \vdash f x_1 \cdot \cdot \cdot x_n = t.\]

(This means that \(f a_1 \cdot \cdot \cdot a_n = t[a_1/x_1, \cdot \cdot \cdot, a_n/x_n]\) for all \(a_1, \cdot \cdot \cdot, a_n \in A\). We say that \(f\) represents \(t\). One may think of \(t\) as a polynomial over the set \(\{x_1, \cdot \cdot \cdot, x_n\}\) of variables and constant symbols from \(A\).
**Proposition 3.3.1 (Characterization)** An applicative structure $A$ is combinatorial complete if and only if $A$ can be given the structure of a combinatorial algebra.

**Proof** "⇒": Given a term $t$ of the required kind, take $f$ to be $\lambda x_1 \cdot \ldots \cdot x_n \cdot t$ where $\text{fv}(t) \subseteq \{ x_1, \ldots, x_n \}$. The result follows by an appeal to Proposition 3.2.1(iv). "⇐": Take $s$ to be the element of $A$ representing $x_1 x_3(x_2 x_3)$ with $n = 3$, and $k$ to be the element of $A$ representing $x_1$ with $n = 2$.

Note that $(cc)$ is equivalent to the following axioms:

\[
\begin{align*}
\exists k, \forall x y, kxy &= x \\
\exists s, \forall x y z, sxyz &= x z(y z).
\end{align*}
\]

Let $e$ denote the term $\lambda x . (\lambda y . x y)$. By Proposition 3.2.1(iv), we have $C_0 \vdash e x y = x y$.

**Lemma 3.3.2** Let $t$ be an $\mathcal{L}$-term and suppose $x$ does not occur free in $t$. Then

\[ C_0 \vdash \lambda x . t x = e t = s(k t)i. \]

**Proof** Any combinatorial algebra validates $e t = \lambda y . t y = s(\lambda y . t)i = s(k t)i$. 

Now consider the axioms:

\[ (C_1) \begin{cases} k = \lambda x y . k x y \\ s = \lambda x y z . s x y z. \end{cases} \]

The following are consequences of $C_0 + C_1$.

\[ k x = \lambda x y . k x y \]

\[ s x y = \lambda z . s x y z; \]

and hence, by Lemma 3.3.2, so are

\[ (C_0^1) \begin{cases} e(k x) = k x \\ e(s x y) = s x y. \end{cases} \]

To summarize we have shown:

**Lemma 3.3.3** $C_0 + C_1 \vdash C_0^1$.

**Proposition 3.3.4 (e-invariance)** The following are consequences of $C_0 + C_1$.

(i) $\lambda x . t = e(\lambda x . t) = \lambda x . (\lambda x . t)x$ i.e. "$e$ fixes any $\lambda$-abstraction"

(ii) $ee = e; e(e x) = e x$. 
Proof (i) The second identity follows from Lemma 3.3.2 as \( x \) does not occur free in \((\lambda x.t)\). Observe that
\[
\lambda x.t = \begin{cases} 
    \text{skk} & \text{or} \\
    kt & \text{or} \\
    suw
\end{cases}
\]
depending on the shape of \( t \). Hence, by \( C_1^0 \), \( e(\lambda x.t) = (\lambda x.t) \).

(ii) The first equation follows from (i) since \( e = \lambda x.(\lambda y.xy) \). By Lemma 3.3.2, \( ex = \lambda y.xy \); the second equation then follows from (i).

\[\square\]

3.4 Extensionality axioms

\textit{Weak extensionality scheme:} for all \( L \)-terms \( t, u \)

\[(\text{WExt}) \quad (\forall x.t = u) \rightarrow \lambda x.t = \lambda x.u.\]

By induction we get as a consequence the scheme

\[(\forall x_1 \cdots x_n.t = u) \rightarrow \lambda x_1 \cdots x_n.t = \lambda x_1 \cdots x_n.u.\]

\textit{Weak extensionality axiom} (which is a formula):

\[(\text{WExt'}) \quad \forall yz.[(\forall x.yx = zx) \rightarrow ey = ez].\]

\textit{Extensionality axiom} is the formula:

\[(\text{Ext}) \quad \forall yz.\{\forall x.[yx = zx] \rightarrow y = z\}.\]

The last axiom says that two elements are equal if and only if they are equal applicatively (or extensionally), i.e., they have the same behaviour as functions.

\textbf{Proposition 3.4.1} \textit{WExt} and \textit{WExt'} are equivalent modulo \( C_0 + C_1 \) (in fact the weaker axiom \( C_0 + C_1^0 \) suffices).

\[\square\]

\textbf{Definition 3.4.2} We denote by \( \text{CL} \) (\textit{combinatory logic}) the system of axioms

\[\text{CL} \overset{\text{def}}{=} C_0 + C_1 + \text{WExt}\]

or equivalently \( C_0 + C_1 + \text{WExt'} \); and by \( \text{ECL} \) (\textit{extensional combinatory logic}) the system of axioms

\[\text{ECL} \overset{\text{def}}{=} C_0 + \text{Ext}\]

Note that in the literature \textit{combinatory logic} is often the name associated with the weaker formal system \( C_0 \), rather than \( \text{CL} \).
3.5 Translation between $\lambda\beta$ and CL

$\lambda$-calculus and combinatory logic are very closely related. As formal theories, they are almost, but not quite, equivalent. The nature of their relationship deserves careful study. There are very natural translations between the two systems. A major question we shall investigate is the extent to which each translation preserves the theory.

First we assume that variables of the first-order language $\mathcal{L}$ coincide with variables of the $\lambda$-calculus. Define maps between $\lambda$-terms and combinatory logic terms

$$\begin{align*}
\Lambda & \xrightarrow{(-)_{\lambda}} (-)_{cl} & \mathcal{L}
\end{align*}$$

where $t \mapsto t_{cl}$ is defined by recursion as follows:

$$\begin{align*}
x_{cl} & \overset{\text{def}}{=} x \\
(tu)_{cl} & \overset{\text{def}}{=} t_{cl}u_{cl} \\
(\lambda x.t)_{cl} & \overset{\text{def}}{=} \lambda x.(t_{cl})
\end{align*}$$

and $a \mapsto a_{\lambda}$ by

$$\begin{align*}
x_{\lambda} & \overset{\text{def}}{=} x \\
(ab)_{\lambda} & \overset{\text{def}}{=} a_{\lambda}b_{\lambda} \\
s_{\lambda} & \overset{\text{def}}{=} \lambda xyz.xz(yz) \\
k_{\lambda} & \overset{\text{def}}{=} \lambda xy.x.
\end{align*}$$

**Lemma 3.5.1** For any terms $a, b$ of $\mathcal{L}$,

(i) if $\mathcal{CL} \vdash a = b$ then $\lambda\beta \vdash a_{\lambda} = b_{\lambda}$

(ii) if $\mathcal{ECL} \vdash a = b$ then $\lambda\beta\eta \vdash a_{\lambda} = b_{\lambda}$. \hfill \Box

**Lemma 3.5.2** (i) For every $\lambda$-term $t$, $\lambda\beta \vdash (t_{cl})_{\lambda} = t$.

(ii) For every $\mathcal{L}$-term $a$, $\mathcal{CL} \vdash (a_{\lambda})_{cl} = a$.

**Proof** For (i) we prove by induction over the structure of $t$. We shall consider only the hardest case of $t \equiv \lambda x.u$. Then $t_{cl} \equiv \lambda x.u_{cl}$. By Proposition 3.2.1(iii), we have $\mathcal{CL} \vdash t_{cl}x = u_{cl}$. Thus by Lemma 3.5.1 $(t_{cl})_{\lambda}x = (u_{cl})_{\lambda}$. By induction hypothesis $(u_{cl})_{\lambda} = u$. Hence $(t_{cl})_{\lambda}x = u$, and so,

$$\lambda x.(t_{cl})_{\lambda}x = \lambda x.u = t.$$

Now since $t_{cl} \equiv \lambda x.u_{cl}$, we have $\mathcal{CL} \vdash e_{t_{cl}} = t_{cl}$, by Proposition 3.3.4(i). Thus $(e_{t_{cl}})_{\lambda} = (t_{cl})_{\lambda}$. But by Proposition 3.3.4(i), $(e_{t_{cl}})_{\lambda} = \lambda x.t_{cl}x_{\lambda} = s(k_{t_{cl}})_{\lambda} = s_{\lambda}(k_{\lambda}(t_{cl})_{\lambda})_{\lambda} = \lambda x.t_{cl}x_{\lambda}$; hence $(t_{cl})_{\lambda} = \lambda x.(t_{cl})_{\lambda}x = t$.

Next we prove (ii) by induction on the size of $a$. The base case of $a$ being a variable is obvious. The inductive case of $a$ being an application is easily checked. Suppose $a$ is $s$. We have ($C_0$): $sxyz = xz(yz)$ for any $x, y, z$. By ($WExt$) we have

$$\lambda xyz.sxyz = \lambda xyz.xz(yz).$$

By ($C_1$), $s = \lambda xyz.xz(yz)$, and so, by definition of $(-)_{\lambda}$ and $(-)_{cl}$, $s = (s_{\lambda})_{cl}$. \hfill \Box
A main result of this section is that the encoding \( \lambda \beta \rightarrow \mathcal{L} \) preserves equations in \( \lambda \beta \) (in the sense of Theorem 3.5.4). To prove it we need a substitution lemma.

**Lemma 3.5.3** For \( u, t \in A \), \( \text{CL} \vdash (u[t/x])_{cl} = u_{cl}[t_{cl}/x] \).

**Proof** By induction on the size of \( u \). The cases of \( u \) being a variable and application are immediate. We only consider the case of \( u \equiv \lambda y . v \).

**Claim:** \( \text{CL} \vdash (u_{cl}[t_{cl}/x])y = (u[t/x])_{cl}y \).

\[
(u[t/x])_{cl}y = (\lambda y . v[t/x])_{cl}y \quad \text{by definition of } (\cdot)_{cl}
\]

\[
= (\lambda y . (v[t/x])_{cl})y \quad \text{by Proposition 3.2.1}
\]

\[
= (v[t/x])_{cl} \quad \text{by induction hypothesis}
\]

\[
= v_{cl}[t_{cl}/x]
\]

\[
= (u_{cl}y)[t_{cl}/x]
\]

\[
= (u_{cl}[t_{cl}/x])y.
\]

But by definition of \( (\cdot)_{cl} \)

\[
u_{cl}y = (\lambda y . v_{cl})y \quad \text{by Proposition 3.2.1}
\]

\[
= v_{cl}.
\]

Hence the claim is proved.

By \( \text{(WExt')} \) from Claim, we have

\[
\text{CL} \vdash e(u_{cl}[t_{cl}/x]) = e(u[t/x])_{cl}
\]

(1)

Now \( u_{cl} \equiv \lambda y . (v_{cl}) \) and \( (u[t/x])_{cl} \equiv \lambda y . (v[t/x])_{cl} \). Hence by Proposition 3.3.4(i)

\[
\text{CL} \vdash e_{u_{cl}} = u_{cl}, \quad \text{and}
\]

(2)

\[
\text{CL} \vdash e(u[t/x])_{cl} = (u[t/x])_{cl}.
\]

(3)

From (2), \( \text{CL} \vdash u_{cl}[t_{cl}/x] = e(u_{cl}[t_{cl}/x]) \). Therefore, from (1) and (3), we get

\[
\text{CL} \vdash u_{cl}[t_{cl}/x] = (u[t/x])_{cl}.
\]

□

**Theorem 3.5.4 (Equivalence)** Let \( t \) and \( u \) be \( \lambda \)-terms. Then

(i) \( \lambda \beta \vdash t = u \) if and only if \( \text{CL} \vdash t_{cl} = u_{cl} \)

(ii) \( \lambda \beta \eta \vdash t = u \) if and only if \( \text{ECL} \vdash t_{cl} = u_{cl} \).
Proof. We shall just prove (i), and leave (ii) as an exercise. "\(\leftarrow\)": If \(\text{CL} \vdash t_{cl} = u_{cl}\) then \((t_{cl})_{\lambda} = (u_{cl})_{\lambda}\). Thus, by Lemma 3.5.2, \(t = u\).

"\(\Rightarrow\)": It suffices to prove it for the case of \(t \rightarrow_{\beta} u\) (one-step \(\beta\)-reduction). We then proceed by induction of the size of \(t\). Clearly \(t\) cannot be a variable. There are two cases. Suppose \(t \equiv \lambda x.t'\). Then \(u \equiv \lambda x.u'\) and \(t' \rightarrow_{\beta} u'\). By the induction hypothesis, \(\text{CL} \vdash t'_{cl} = u'_{cl}\). By \(\text{WExt}^\prime\), \(\text{CL} \vdash \lambda x.(t'_{cl}) = \lambda x.(u'_{cl})\). Hence \(\text{CL} \vdash (\lambda x.t')_{cl} = (\lambda x.u')_{cl}\).

Now suppose \(t \equiv pq\). There are three subcases.

- \(\lambda x.tw\) and \(u \equiv v[w/x]\): by Lemma 3.5.3, \(\text{CL} \vdash u_{cl} = v_{cl}[w_{cl}/x]_{cl}\); on the other hand, \(t_{cl} \overset{\text{def}}{=} (\lambda x.v_{cl})w_{cl}\). Hence by Proposition 3.2.1, \(\text{CL} \vdash t_{cl} = u_{cl}\).

Problems

3.1 Show that \(\lambda x.y.yx \equiv s(k(s))\). What is \(\lambda x.y.y(x)\)?

3.2 Basis. Let \(\mathcal{L}\) be a collection of \(\lambda\)-terms. The set \(\mathcal{L}^+\) of terms generated by \(\mathcal{L}\) is the least set \(\mathcal{P}\) such that

- \(\mathcal{L} \subseteq \mathcal{P}\)
- if \(s, t \in \mathcal{P}\) then \(st \in \mathcal{P}\).

Let \(\mathcal{Q} \subseteq \mathcal{L}\). \(\mathcal{L} \subseteq \mathcal{A}\) is said to be a basis for \(\mathcal{Q}\) just in case for every \(q \in \mathcal{Q}\), there is some \(t_q \in \mathcal{L}^+\) such that \(\lambda \beta \vdash t_q = q\). \(\mathcal{L}\) is a basis if \(\mathcal{L}\) is a basis for \(\lambda^0\) (the set of closed \(\lambda\)-terms).

Prove that \(\{k, s\}\) is a basis. [Hint: Use Lemma 3.5.2]

3.3 Show that \(\lambda x.xkksk\) is a singleton basis. [Hint: Calculate \(\theta\theta\theta\) and \(\theta(\theta\theta)\).]

3.4 (i) (Barendregt) Let \(X \equiv \lambda x.xs(kk)k\). Show that \(\{X\}\) is a basis. [Hint: calculate \(XXX\) and \(Xk\).]

(ii) (Rosser) Find a closed \(\lambda\)-term \(J\) such that \(JJ = s\) and \(Js = k\).

3.5 Prove Proposition 3.7.

3.6 Prove Lemma 3.5.1.

3.7 Show that the set of closed \(\lambda\)-terms quotiented by \(\beta\)-equivalence is a model of \(\text{CL}\). Hence or otherwise prove Proposition: \(\text{WExt}^\prime\) and \(\text{WExt}^\prime\) are equivalent modulo \(C_0 + C_1\) (in fact the weaker axiom \(C_0 + C_1^0\) suffices).
3.8 The **weak combinatory logic** notion of reduction is given by the union of the following binary relations (defined schematically): $p, q$ and $r$ range over combinatory logic terms

\[
\langle kpq, \ p \rangle \\
\langle spqr, \ pr(qr) \rangle
\]

Show that the corresponding one-step weak reduction $\rightarrow_w$ is Church-Rosser.

[Hint (Rosser 1935): Define $s > t$ just in case there are disjoint weak-redexes $\Delta_1, \cdots, \Delta_n$ in $s$, and $t$ is obtained by contracting them. For example $s(kpq)(spqr) > sp(pr(qr))$. Show that

(i) $>$ satisfies the diamond property

(ii) $\rightarrow_w$ is the transitive closure of $>$.]

4 Böhm’s Theorem

Böhm’s theorem was proved in the late ’60s and remains possibly the most significant discovery in the syntax of untyped λ-calculus. It gives rise to a powerful technique for obtaining separability results.

4.1 The theorem and its significance

**Theorem 4.1.1 (Böhm)** Let \( s \) and \( t \) be closed normal λ-terms that are not \( βη \)-equivalent. Then there exist closed terms \( u_1, \ldots, u_k \) such that

\[
\begin{align*}
\bar{s}u_1 &= f \\
\bar{t}u_1 &= t.
\end{align*}
\]

where \( t \equiv \lambda xy.x \) and \( f \equiv \lambda xy.y \).

**Exercise 4.1.2** Show that \( t \) and \( f \) of the theorem can be replaced by any pair of closed \( β \)-normal forms that are not \( βη \)-equivalent.

Böhm’s theorem is a classic result in the syntax of untyped λ-calculus. It is a powerful separability result.

An aside on λ-theories

A λ-theory is a consistent extension of \( λβ \) that is closed under provability. A (closed) equation is a formula of the form \( s = t \) where \( s \) and \( t \) are closed λ-terms. If \( T \) is a set of closed equations, then the theory \( λβ + T \) is obtained from \( λβ \) by augmenting the axioms by \( T \).

**Definition 4.1.3** Let \( T \) be a set of closed equations. \( T^+ \) is the set of closed equations provable in \( λβ + T \). We say that \( T \) is a λ-theory just in case \( T = T^+ \) and \( T \) is consistent (i.e. there are terms \( s \) and \( t \) such that \( s = t \) is not provable in \( T \)).

**Corollary 4.1.4** Any λ-theory which identifies any two closed normal λ-terms that are not \( βη \)-equivalent is inconsistent.

**Proof** Take any λ-terms \( A \) and \( B \). Write

\[
D \equiv \lambda xyz. zyx.
\]

Then we have

\[
DsB \equiv A \\
DsA \equiv B.
\]

Hence if \( L \vdash s = t \) where \( s \) and \( t \) are any closed normal λ-terms that are not \( βη \)-equivalent, then for the \( u \) given by the theorem, we have \( L \vdash DAB(su) = DAB(tu) \), and so,

\[
L \vdash A = B.
\]

The so-called “Böhm-out technique” is crucial to the proof of most local structure characterization theorems of λ-models.
4.2 Proof of the theorem

First some notations. The **permutator of order** $n$ is defined to be the following term

$$
\alpha_n \overset{\text{def}}{=} \lambda x_1 \cdots x_n.x.x_1 \cdots x_n.
$$

**Definition 4.2.1** We shall call **Böhm transformation** any function from $\Lambda$ (the collection of $\lambda$-terms) to $\Lambda$ defined by composing basic functions of the form $t \mapsto tu_0$ or $t \mapsto t[u_0/x]$ where $u_0$ and $x$ are a given term and variable respectively.

We shall denote the functions as follows:

$$
B_{u_0} : t \mapsto tu_0
$$

$$
B_{u_0,x} : t \mapsto t[u_0/x].
$$

**Lemma 4.2.2** For every Böhm transformation $B$, there are terms $u_1, \ldots, u_k$ such that $Bs = su_1 \cdots u_k$ for every closed term $s$. \hfill \Box

**Exercise 4.2.3** Prove the lemma.

**Lemma 4.2.4** Let $s, t$ be two $\lambda$-terms. If one of the following

1. $s \equiv xs_1 \cdots s_p$
2. $s \equiv \lambda x_1 \cdots x_m.xs_1 \cdots s_p$

holds then

$$
\begin{align*}
Bs &= f \\
Bt &= t
\end{align*}
$$

for some Böhm transformation $B$.

**Proof** Case (1):

(i) $x \neq y$, take $\sigma \equiv \lambda z_1 \cdots z_p.f$ and $\tau \equiv \lambda z_1 \cdots z_q.t$. Take $B$ to be $B_{\sigma,x} \circ B_{\tau,y}$. Then

$$
Bs = f
$$

$$
Bt = t.
$$

(ii) $x = y$ and $p < q$. Then

$$
B_{\alpha_q,x}s = \alpha_q s_1^* \cdots s_p^* = \lambda z_{p+1} \cdots z_q.zs_1^* \cdots s_p^*z_{p+1} \cdots z_q
$$

$$
B_{\alpha_q,x}t = \alpha_q t_1^* \cdots t_q^* = \lambda z.zt_1^* \cdots t_q^*
$$

where $(\cdot)^*$ means $(\cdot)[\alpha_q/x]$. This is case (2)(i).
4.2 Proof of the theorem

Case (2):

(i) \( m \neq n \), say \( m < n \); take distinct variables \( z_1, \ldots, z_n, z \) not occurring in \( s, t \). Let

\[
B \equiv B_z \circ B_{z_n} \circ \cdots \circ B_{z_1}.
\]

Then

\[
Bs = z_{m+1}s_1^* \cdots s_p^* z_{m+2} \cdots z_n^*
\]

where \((\cdot)^*\) is \((\cdot)[z_1/x_1, \ldots, z_m/x_m, z_{m+1}/x]\), and

\[
Bt = z_{t_1}^{\dagger} \cdots t_q^{\dagger}
\]

where \((\cdot)^\dagger\) is \((\cdot)[z_1/x_1, \ldots, z_n/x_n, z/x]\). This is just case (1)(i).

(ii) \( m = n \) and \( p \neq q \); let \( B \equiv B_x \circ B_{x_m} \circ \cdots \circ B_{x_1} \). We have

\[
Bs = xs_1 \cdots s_p
\]

\[
Bt = xt_1 \cdots t_q
\]

This is just case (1)(ii).

Note: cases (2)(ii) \( \rightarrow \) (1)(ii) \( \rightarrow \) (2)(i) \( \rightarrow \) (1)(i).

\[\blacksquare\]

**Theorem 4.2.5** Let \( s \) and \( t \) be non-\( \eta \)-equivalent normal \( \lambda \)-terms, and \( x_1, \ldots, x_k \) any distinct variables. Then for any \( n_1, \ldots, n_k \), provided they are large enough, there is a Böhm transformation \( B \) such that

\[
\begin{align*}
B(s[\alpha_{n_1}/x_1, \ldots, \alpha_{n_k}/x_k]) &= f \\
B(t[\alpha_{n_1}/x_1, \ldots, \alpha_{n_k}/x_k]) &= t.
\end{align*}
\]

**Proof** The size \( \text{size}(s) \) of a term \( s \) is defined by recursion as follows:

\[
\begin{align*}
\text{size}(x) &\equiv 1 \\
\text{size}(st) &\equiv \text{size}(s) + \text{size}(t) \\
\text{size}(\lambda x.s) &\equiv \text{size}(s) + 2.
\end{align*}
\]

We prove by induction on \( \text{size}(s) + \text{size}(t) \).

Case analysis:

(1) \( s \) and \( t \) are both abstractions

(2) only one of \( s \) and \( t \) is an abstraction

(3) both are not abstractions.
Claim: It suffices to consider the last case.

Proof of Claim Take \( y \neq x_1, \cdots, x_k \) with no occurrence in \( s \) and \( t \), and let \( w_s \) and \( w_t \) be the normal form of \( sy \) and \( ty \) respectively. Now \( w_s \) is not \( \beta \eta \)-equivalent to \( w_t \) (why?). Suppose case (1), say \( s \equiv \lambda x.u \) and \( t \equiv \lambda x'.u \) then \( w_s \equiv u[y/x], w_t \equiv v[y/x'] \) and

\[
\text{size}(w_s) + \text{size}(w_t) = \text{size}(s) + \text{size}(t) - 4.
\]

Suppose case (2), say, \( s \equiv \lambda x.u \) and \( t \) is not an abstraction, then either \( t \) is a variable or \( v_1 v_2 \). Thus \( w_s \equiv u[y/x] \) and \( w_t \equiv ty \) and

\[
\text{size}(w_s) + \text{size}(w_t) = \text{size}(s) + \text{size}(t) - 1.
\]

Hence, in both cases, we can apply the induction hypothesis to \( w_s \) and \( w_t \). Suppose for any \( n_1, \cdots, n_k \) there exists \( B \) such that

\[
\begin{align*}
B(w_s[\alpha_{n_1}/x_1, \cdots, \alpha_{n_k}/x_k]) &= f \\
B(w_t[\alpha_{n_1}/x_1, \cdots, \alpha_{n_k}/x_k]) &= t.
\end{align*}
\]

Take the Böhm transformation \( B \circ B_y \) which works for \( s \) and \( t \).

We shall consider the case where both \( s \) and \( t \) are not abstractions, say

\[
s \equiv x s_1 \cdots s_p \]
\[
t \equiv y t_1 \cdots t_q
\]

where \( s_i, t_j \) are all normal forms.

Fix distinct numbers \( n_1, \cdots, n_k \) and variables \( x_1, \cdots, x_k \). We write

\[
(-)^* \text{ for } (-)[\alpha_{n_1}/x_1, \cdots, \alpha_{n_k}/x_k].
\]

There are three subcases:

Case (i): \( x, y \notin \{ x_1, \cdots, x_k \} \).

We have

\[
s^* \equiv x s_1^* \cdots s_p^* \\
t^* \equiv y t_1^* \cdots t_q^*
\]

If \( x \neq y \) or \( p \neq q \) then result follows from Lemma 4.2.4. If \( x = y \) and \( p = q \) take any number \( n > p, n_1, \cdots, n_k \). Then take \( B = B_{x} \circ B_{z_n} \cdots \circ B_{z_{p+1}} \circ B_{z_{n}}.x \). We have

\[
Bs^* = zs_1^t \cdots s_p^t z_{p+1} \cdots z_n
\]
\[
Bt^* = zt_1^t \cdots t_q^t z_{p+1} \cdots z_n
\]

where \((-)^t\) is \((-)[\alpha_{n_1}/x_1, \cdots, \alpha_{n_k}/x_k, \alpha_n/x].\)
4.2 Proof of the theorem

Since $s$ and $t$ are not $\beta\eta$-equivalent, for some $i$, $s_i$ and $t_i$ are not $\beta\eta$-equivalent. Take $\pi_i \equiv \lambda x_1 \cdots x_n. x_i$.

\[
B_{\pi_i, z} \circ B(s^*) = s_i^*
\]
\[
B_{\pi_i, z} \circ B(t^*) = t_i^*
\]

(Note that $z$ does not occur free in $s_i^*$ or $t_i^*$.) Clearly $\text{size}(s_i) + \text{size}(t_i) < \text{size}(s) + \text{size}(t)$. Hence, by the induction hypothesis, say $B'$ is the required Böhm transformation for $s_i^*$ and $t_i^*$. The Böhm transformation required is just $B' \circ B_{\pi_i, z} \circ B$.

Case (ii): $x \in \{ x_1, \ldots, x_k \}$, say, $x = x_1$, and $y \notin \{ x_1, \ldots, x_k \}$. Then, for every $n_1 > p$,

\[
s^* = \alpha_{n_1} s_1^* \cdots s_p^* = \lambda z_{p+1} \cdots z_{n_1} z. z_1 s_1^* \cdots s_p^* z_{p+1} \cdots z_{n_1}
\]
\[
t^* = yt_1^* \cdots t_q^*,
\]

Take $B = B_z \circ B_{z_{n_1}} \circ \cdots \circ B_{z_{p+1}}$,

\[
B(s^*) = z s_1^* \cdots s_p^* z_{p+1} \cdots z_{n_1},
\]
\[
B(t^*) = y t_1^* \cdots t_q^* z_{p+1} \cdots z_{n_1} z.
\]

Since $y \neq z$, result follows from Lemma 4.2.4(1).

Case (iii): $x, y \in \{ x_1, \ldots, x_k \}$.

Suppose $x = x_1$ and $y = x_2$ are distinct:

\[
s^* = \alpha_{n_1} s_1^* \cdots s_p^* = \lambda z_{p+1} \cdots z_{n_1} z. z_1 s_1^* \cdots s_p^* z_{p+1} \cdots z_{n_1}
\]
\[
t^* = \alpha_{n_1} t_1^* \cdots t_q^* = \lambda z_{q+1} \cdots z_{n_1} z. t_1^* \cdots t_q^* z_{q+1} \cdots z_{n_2}
\]

taking $n_1 > p$, $n_2 > q$. Since $n_1 \neq n_2$ result follows from Lemma 4.2.4(2).

Suppose $x = y = x_1$, take $n_1 > p, q$:

\[
s^* = \alpha_{n_1} s_1^* \cdots s_p^* = \lambda z_{p+1} \cdots z_{n_1} z. z_1 s_1^* \cdots s_p^* z_{p+1} \cdots z_{n_1}
\]
\[
t^* = \alpha_{n_1} t_1^* \cdots t_q^* = \lambda z_{q+1} \cdots z_{n_1} z. t_1^* \cdots t_q^* z_{q+1} \cdots z_{n_1}.
\]

If $p \neq q$ then by Lemma 4.2.4(2), $n_1 - p \neq n_1 - q$, result then follows. If $p = q$ then since $s$ and $t$ are not $\beta\eta$-equivalent, for some $i$, $s_i$ and $t_i$ are not $\beta\eta$-equivalent. Let $\pi_1 \equiv \lambda x_1 \cdots x_n. x_i$ and $B \overset{\text{def}}{=} B_z \circ B_{z_{n_1}} \circ \cdots \circ B_{z_{p+1}}$. Then

\[
B_{\pi_1, z} \circ B(s^*) = s_i^*
\]
\[
B_{\pi_1, z} \circ B(t^*) = t_i^*.
\]

Similar argument as before concludes the proof. \qed

Böhm's Theorem is an immediate consequence of Theorem 4.2.5. For if $s$ is any closed term and $B$ a Böhm transformation, then by Lemma 4.2.2 we have $B s = s u_1 \cdots u_k$ where $u_1, \ldots, u_k$ depend only on $B$. By applying Theorem 4.2.5 we therefore obtain $s u_1 \cdots u_k = \text{f}$ and $t u_1 \cdots u_k = \text{t}$. (We may suppose that $\bar{u}$ are closed terms.)
5 Call-by-name and call-by-value lambda calculi

According to the so-called function paradigm of computation, the goal of every computation is to determine its value. Thus to compute is to evaluate. A (by now) standard way to implement evaluation is by a process of reduction. In this section we shall investigate a couple of important ideas that have arisen in semantics of functional computation in recent years. We take pure, untyped \(\lambda\)-calculus equipped with call-by-name (CBN) and call-by-value (CBV) reduction strategies as minimal (and prototypical) functional languages; and consider two operational or behavioural preorders over terms, namely, applicative simulation and observational (or contextual) preorder. We prove that they coincide in both CBN and CBV \(\lambda\)-calculi. In other words both languages satisfy the context lemma.

5.1 Motivations

The commonly accepted basis for functional programming is the \(\lambda\)-calculus; and it is folklore that the \(\lambda\)-calculus is the prototypical functional language in purified form. But what is the \(\lambda\)-calculus? The syntax is simple and classical; variables, abstraction and application in the pure calculus, with applied calculi obtained by adding constants. The further elaboration of the theory, covering conversion, reduction, theories and models, is laid out in Barendregt’s already classical treatise [Bar84]. It is instructive to recall the following crux, which occurs rather early in that work (p. 39):

Meaning of \(\lambda\)-terms: first attempt

- The meaning of a \(\lambda\)-term is its normal form (if it exists).
- All terms without normal forms are identified.

This proposal incorporates such a simple and natural interpretation of the \(\lambda\)-calculus as a programming language, that if it worked there would surely be no doubt that it was the right one. However, it gives rise to an inconsistent theory!

Second attempt: sensible theory

- The meaning of \(\lambda\)-terms is based on head normal forms via the notion of Böhm tree.
- All unsolvable terms (no head normal form) are identified.

This second attempt forms the central theme of Barendregt’s book, and gives rise to a very beautiful and successful theory (henceforth referred to as the “standard theory”), as that work shows.

This, then, is the commonly accepted foundation for functional programming; more precisely, for the lazy functional languages [FW76, HM76], which represent the mainstream of current functional programming practice. Examples: Miranda [Tur85], LML [Aug84], Orwell [Wad85], Haskell, and Gofer. But do these languages as defined and implemented actually evaluate terms to head normal form? To the best of our knowledge, not a single one of them does so. Instead, they evaluate to weak head normal form i.e. they do not evaluate under abstractions (see [PJ87] for a comprehensive survey of the pragmatics of functional programming languages). E.g., \(\lambda x.(\lambda y.y)s\) is in weak head normal form, but not in head normal form, since it contains the head redex \((\lambda y.y)s\).

So we have a fundamental mismatch between theory and practice. Since current practice is well-motivated by efficiency considerations and is unlikely to be abandoned readily, it makes sense to see if a good modified theory can be developed for it. To see that the theory really does need to be modified, we consider the following example.
Example 5.1.1 Let \( \Omega \equiv (\lambda x.xx)(\lambda x.xx) \) be the standard unsolvable term. Then \( \lambda x.\Omega = \Omega \) in the standard theory, since \( \lambda x.\Omega \) is also unsolvable; but \( \lambda x.\Omega \) is in weak head normal form, hence should be distinguished from \( \Omega \) in our “lazy” theory.

We now turn to a second point in which the standard theory is not completely satisfactory.

Is the \( \lambda \)-calculus a programming language?

In the standard theory, the \( \lambda \)-calculus may be regarded as being characterized by the type equation

\[
D = [D \rightarrow D]
\]

(for justification of this in a general categorical framework, see e.g. [Sco80, Koy82, LS86]).

It is one of the most remarkable features of the various categories of domains used in denotational semantics that they admit non-trivial solutions of this equation. However, there is no canonical solution in any of these categories (in particular, the initial solution is trivial – the one-point domain).

We regard this as a symptom of the fact that the pure \( \lambda \)-calculus in the standard theory is not a programming language. Of course, this is to some extent a matter of terminology, but we feel that the expression “programming language” should be reserved for a formalism with a definite computational interpretation (an operational semantics). The pure \( \lambda \)-calculus as ordinarily conceived is too schematic to qualify.

5.2 Call-by-name or Lazy \( \lambda \)-calculus

We introduce a “toy” functional language that has closed \( \lambda \)-terms as programs and (closed) abstractions as values. The operational semantics is given by a Martin-Löf style evaluation relation (which is also known as “big-step” reduction relation) simulating a normal order (or leftmost) reduction strategy that terminates whenever the reduction reaches a weak head normal form (WHNF).

Definition 5.2.1 We define a family \( \Downarrow_n \) of binary relations over closed \( \lambda \)-terms as follows. For each \( n \), the relation \( s \Downarrow_n v \) (“the program \( s \) converges to value \( v \) in \( n \) steps”) is defined inductively by the following rules:

\[
\begin{align*}
\lambda x.p & \Downarrow_0 \lambda x.p \\
s \Downarrow_n \lambda x.p & \quad p[t/x] \Downarrow_n v \\
\Downarrow^{m+n+1}_n v
\end{align*}
\]

Notation It is useful to fix some shorthand.

\[
\begin{align*}
s \Downarrow v & \overset{\text{def}}{=} \exists n \in \omega, s \Downarrow_n v \quad \text{“} s \text{ converges to } v \text{”} \\
s \Downarrow & \overset{\text{def}}{=} \exists v, s \Downarrow v \quad \text{“} s \text{ converges”} \\
s \Downarrow & \overset{\text{def}}{=} \neg [s \Downarrow] \quad \text{“} s \text{ diverges”}
\end{align*}
\]

For example, \( i(ii) \Downarrow i \) and \( k(ii) \Downarrow \lambda y.y \), and \( \Omega \Downarrow \). Take a \( \lambda \)-term \( s \) that is not in \( \beta \)-normal form. Informally the leftmost \( \beta \)-redex of \( s \) is the redex that literally “occurs leftmost” in \( s \). We define a reduction strategy informally: at each step, contract the leftmost redex and stop as soon as an abstraction (weak head normal form) is reached. Convince yourself that for any program \( s, s \Downarrow v \) if and only if \( s \) reduces to \( v \) by the reduction strategy.

Proposition 5.2.2 (i) Show that \( (\lambda x.p)t \Downarrow_{n+1} v \iff p[t/x]t \Downarrow_n v \).

(ii) Prove that \( \Downarrow \) is deterministic i.e. it defines a partial function from programs to values: whenever \( s \Downarrow v \) and \( s \Downarrow v' \) then \( v \) and \( v' \) are the same. \( \square \)
The CBN $\lambda$-calculus was first introduced by Plotkin in [Plo75]. An extensive study of the calculus can be found in [AO93].

5.3 Applicative simulation and context lemma

Under the reduction strategy $\downarrow$, the possible “results” are of a particularly simple, indeed atomic kind. That is to say, a term $s$ either converges to an abstraction (and according to this strategy, we have no clue as to the structure “under” the abstraction), or it diverges. The relation $\downarrow$ by itself is too “shallow” to yield information about the behaviour of a term under all experiments.

Inspired by the work of Robin Milner [Mil80] and David Park [Par80] on concurrency, we shall use the reduction relation $\downarrow$ as a building block to yield a deeper relation which we call applicative simulation. To motivate this relation, let us spell out the observational scenario we have in mind: Given a closed term $s$, the only experiment of depth 1 we can do is to evaluate $s$ and see if it converges to some abstraction (weak head normal form) $\lambda x.p_1$. If it does so, we can continue the experiment to depth 2 by supplying a term $t_1$ as input to $\lambda x.p_1$, and so on. Note that what the experimenter can observe at each stage is only the fact of convergence, not which term lies under the abstraction. We can picture matters thus:

Stage 1 of experiment: $s \downarrow \lambda x.p_1$;
environment “consumes” $\lambda$,
produces $t_1$ as input

Stage 2 of experiment: $p_1[t_1/x] \downarrow \ldots$

Definition 5.3.1 We define a family of binary relations $\equiv_k (k \in \omega)$ over $\Lambda^0$ as follows:

- for any $s$ and $s'$, $s \equiv_0 s'$.
- $s \equiv_{k+1} s'$ provided $\forall \lambda x.p.[s \downarrow \lambda x.p] \implies \exists \lambda x.p'.[s' \downarrow \lambda x.p' \& \forall r \in \Lambda^0.p'[r/x] \equiv_k p'[r/x]]$.

We then define $s \equiv s'$ to be $s \equiv_k s'$ for all $k \in \omega$. The definition can be extended to all $\lambda$-terms by considering closures in the usual way i.e. for $s, s' \in \Lambda$,

$s \equiv s' \; \text{def} \; \forall \sigma : \text{var} \rightarrow \Lambda^0. s_\sigma \equiv s'_\sigma$

where $s_\sigma$ means the “term that is obtained from $s$ by simultaneously substituting $\sigma(x)$ for each free occurrence of $x$, with $x$ ranging over the collection var of $\lambda$-calculus variables”. For example $\Omega \equiv x$ and $\Omega x \equiv x$.

Write $s \sim s'$ to mean $s \equiv s'$ and $s' \equiv s$; and set

$\lambda \equiv \{ s = t : s \sim t \text{ where } s, t \in \Lambda^0 \}$.

We say that $s$ and $s'$ are applicatively bisimilar or simply bisimilar just in case $s \sim s'$. The theory $\lambda \equiv$ is clearly (non-trivial and) consistent.
Exercise 5.3.2  
(i) Show that \( \leq \) is a preorder over \( \Lambda \) i.e., a reflexive and transitive binary relation.
(ii) Show that \( (\lambda x.x)(\lambda x.x) \sim (\lambda x.x)(\lambda x.x) \) \( \leq \lambda x.(\lambda x.x)(\lambda x.x) \); show that \( \lambda x.x \), \( k \) and \( s \) are pairwise incompatible w.r.t. \( \leq \).
(iii) Suppose \( s \uparrow \) and \( t \downarrow \). Show that \( \lambda x_1 \cdots x_n.s \leq \lambda x_1 \cdots x_n.t \).
(iv) Show that \( \lambda x_1 \cdots x_m.s \leq \lambda x_1 \cdots x_m.s \) iff \( n \leq m \).

For an alternative description of \( \leq \), recall that the set \( \mathcal{R} \) of binary relations over \( \Lambda^\omega \) is a complete lattice under set inclusion. Now, define \( F : \mathcal{R} \to \mathcal{R} \) by

\[
F(R) \overset{\text{def}}{=} \{ (s, s') : \forall \lambda x.p. [s \downarrow \lambda x.p \implies \exists s' \downarrow \lambda x.q' \land \forall t \in \Lambda^\omega. ([p[t/x], p'[t/x]] \in R)] \}
\]

It is easy to check that \( F \) is a monotone function with respect to the inclusion ordering. A relation \( R \in \mathcal{R} \) is said to be a pre-simulation just in case \( R \subseteq F(R) \) i.e. \( R \) is a post-fixpoint of \( F \). Since \( F \) is monotone, by Tarski’s Theorem [Tar55], it has a maximal pre-simulation given by

\[
\bigcup_{R \subseteq F(R)} R
\]

since the closure ordinal [Mos74] of \( \langle \leq_k : k \in \omega \rangle \) is \( \omega \). Note that the maximal post-fixpoint of \( F \) is also its maximal fixpoint (and this holds generally).

Lemma 5.3.3 Applicative simulation is precisely the maximal pre-simulation. \( \square \)

We give a useful characterization of \( \leq \).

Theorem 5.3.4 (Characterization) For any \( s, s' \in \Lambda^\omega \), \( s \leq s' \) if and only if for any finite (possibly empty) sequence \( \ell \) of closed \( \lambda \)-terms, if \( s \ell \downarrow \) then \( s' \ell \downarrow \). \( \square \)

To prove the theorem, we first establish a useful result:

Lemma 5.3.5  
(i) If \( s \downarrow \lambda x.p \) and \( s' \downarrow \lambda x.q' \) then for any \( r \in \Lambda^\omega \), for any \( n \geq 0 \),

\[
s r \leq_n s' r \iff p[r/x] \leq_n q'[r/x].
\]

(ii) Hence if \( s \) and \( s' \) are both convergent then \( s \leq_{n+1} s' \iff \forall r \in \Lambda^\omega. s r \leq_n s' r \).

Proof  
(i) The case of \( n = 0 \) is vacuous. Assume \( s \downarrow \lambda x.p \) and \( s' \downarrow \lambda x.q' \). Then \( s r \downarrow \lambda y.q \) iff \( p[r/x] \downarrow \lambda y.q \), and \( s' r \downarrow \lambda y.q' \) iff \( p'[r/x] \downarrow \lambda y.q' \). Now for the case of \( n = l + 1 \): by definition, \( s r \leq_{l+1} s' r \) iff if \( s r \downarrow \lambda y.q \) then \( s' r \downarrow \lambda y.q' \) and for any closed \( t \), \( q[t/y] \leq q'[t/y] \); i.e. iff \( p[r/x] \downarrow \lambda y.q \) then \( p'[r/x] \downarrow \lambda y.q' \) and for any closed \( t \), \( q[t/y] \leq q'[t/y] \); i.e. iff \( p[r/x] \leq_{l+1} p'[r/x] \). (ii) follows from (i) and the definition of \( \leq_{l+1} \). \( \square \)

We define a family of relations \( \leq_n \) with \( n \geq 0 \): \( s \leq_0 s' \) holds for any \( s \) and \( s' \); for \( n \geq 0 \) we define \( s \leq_n s' \) by “for any finite sequence \( \ell = t_1, \ldots, t_m \) such that \( m < n \), if \( s \ell \downarrow \) then \( s' \ell \downarrow \)”. To prove the theorem, it suffices to show:

for all \( n \geq 0 \), \( \leq_n \) and \( \leq \) are equal.
We shall prove it by induction on \( n \). The base case is obvious. For the inductive case of \( n = l + 1 \), we may assume w.l.o.g. that \( s \) and \( s' \) are both convergent. Observe that \( s \ll_{n+1} s' \) iff “whenever \( s \downarrow \) then \( s' \downarrow \), and for any closed \( t \), \( st \ll_n s't \). Hence

\[
s \ll_{l+1} s' \quad \text{by the preceding and assumption}
\]

\[
\iff \forall t. st \ll_l s't \quad \text{by induction hypothesis}
\]

\[
\iff \forall t. st \ll_l s't \quad \text{by Lemma 5.3.5(ii)}
\]

\[
\iff s \ll_{l+1} s'.
\]

Hence the theorem is proved.

Recall that programs are closed terms. Thus program contexts are just closed contexts i.e. contexts that have no free \( \lambda \)-variables. We say that \( s \) observationally approximates \( s' \) just in case for any program context \( C[X] \), if \( C[s] \) converges then so must \( C[s'] \). Informally this means that whatever we can observe about \( s \), the same can be observed about \( s' \). (Note that convergence is the only thing we can observe about a computation in the CBN \( \lambda \)-calculus.)

**Definition 5.3.6** The binary relation \( \ll^{\text{ctx}} \) over \( \Lambda^0 \), called observational or contextual preorder is defined as

\[
s \ll^{\text{ctx}} s' \quad \text{def} \quad \forall C[X] \in \Lambda^0. C[s] \downarrow \implies C[s'] \downarrow.
\]

Observational equivalence captures the intuitive idea that two program fragments are indistinguishable in all possible programming contexts. Though observational preorder is clearly important, it is hard to reason about it directly. Try proving that \( \lambda x.x \Omega \ll^{\text{ctx}} \lambda x.xx \) or \( \lambda x.xx \ll^{\text{ctx}} \lambda x.(\lambda y.x) \). Fortunately there is a convenient characterization.

**Proposition 5.3.7 (Context lemma)** Applicative simulation and context preorder coincide.

**Proof** This is a variation of Berry’s proof of a Context Lemma in [Ber81].

It suffices to prove the following: Let \( s, s' \) range over \( \Lambda^0 \).

\[
s \ll s' \implies \forall l \in \omega. \forall C[X] \in \Lambda^0. C[s] \downarrow_l \implies C[s'] \downarrow_l.
\]

We prove the assertion by induction on \( l \). The base case is obvious. Without loss of generality, consider the following two cases of closed contexts:

1. \( C[X] \equiv \lambda x.P[X](Q[X])R[X] \),
2. \( C[X] \equiv X(P[X])Q[X] \).

(1): Suppose \( C[s] \downarrow_{l+1} \). Define \( D[X] \equiv (P[X])[Q[X]/x]R[X] \). Then by Proposition 5.2.2 \( D[s] \downarrow_l \). Invoking the induction hypothesis, we have \( D[s'] \downarrow_l \), which implies that \( C[s'] \downarrow_l \).

(2): Let \( s \equiv (\lambda x.p)\bar{q} \). Suppose \( C[s] \downarrow_{l+1} \). Define \( D[X] \equiv (\lambda x.p)(P[X])Q[X] \), a context of case (1). Note that \( C[s] \equiv D[s] \). By an appeal to (1), we have \( D[s'] \downarrow_l \). But \( D[s'] \equiv sP[s']Q[s'] \), and so by Theorem 5.3.4, because \( s \ll s' \), we have \( s'P[s']Q[s'] \downarrow_l \), i.e. \( C[s'] \downarrow_l \). \( \square \)
Remark 5.3.8 (i) The above result says that if two programs are distinguishable by some program context then there is some applicative context that distinguishes them. In other words, the computational behaviour of cbn \( \lambda \)-calculus program is functional, which is what one would expect of a functional programming language. This property is called \textit{operational extensionality} in [Blo88]. Milner [Mil77] proved a similar result in the case of simply typed combinatory algebra which he referred to as the \textit{Context Lemma}.

(ii) It follows immediately from the definition of \( \equiv \) that the application operation in \( \Lambda^o \) is monotone in the left argument with respect to \( \equiv \). Operational extensionality is equivalent to the monotonicity of the application operation in the right argument, i.e.

\[
s \equiv s' \implies \forall t \in \Lambda^o. ts \equiv ts';
\]

which is the same as saying that \( \equiv \) is a \textit{precongruence} i.e.

\[
s \equiv s' \land t \equiv t' \implies st \equiv s't'.
\]

5.4 Call-by-value \( \lambda \)-calculus

We let \( p, r, s \) and \( t \) range over \( \lambda \)-terms. \textit{Programs} of Plotkin’s call-by-value (cbv) \( \lambda \)-calculus are closed \( \lambda \)-terms, and \textit{values}, ranged over by \( u \) and \( v \), are closed abstractions. Evaluation is defined by induction over the following rules: for programs \( \lambda x.p, s \) and \( t \)

\[
\lambda x.p \downarrow \lambda x.p \quad s \downarrow \lambda x.p \quad t \downarrow u \quad p[u/x] \downarrow v.
\]

As before we read \( s \downarrow v \) as “program \( s \) converges or evaluates to value \( v \)”, and write \( s \downarrow \) to mean \( s \downarrow v \) for some value \( v \).

\textbf{Notation:} We shall not bother to distinguish notationally the evaluation relation of the cbv \( \lambda \)-calculus from that of the cbn \( \lambda \)-calculus, though they are of course distinct relations.

We present the operational semantics in terms of a \textit{Plotkin-style transition relation} (which is also known as \textit{“small-step” reduction relation}) by induction over the following rules:

\[
(\lambda x.p)v > p[v/x] \quad \frac{s > s'}{E[s] > E[s']}
\]

where \( E[X] \) ranges over the collection of \textit{evaluation contexts} defined by the following rules: \( v \) and \( s \) range over values and programs respectively

- \( X \) is an evaluation context
- if \( E \) is an evaluation context, then so is \( vE \)
- if \( E \) is an evaluation context, then so is \( Es \).

Note that by definition, the hole occurs exactly once in every evaluation context. We call a term of the shape \( (\lambda x.p)v \) a \textit{cbv} \( \beta \)-redex, and write \( \gg \) to be the reflexive, transitive closure of \( > \).

\textbf{Lemma 5.4.1 (Evaluation context)} For any program \( s, s > s' \) iff there is a unique evaluation context \( E[X] \) and a unique cbv redex \( \Delta \equiv (\lambda x.p)v \) such that \( E[\Delta] \equiv s \) and \( s' \equiv E[p[v/x]]. \) Hence big-step (Martin-Löf style evaluation relation) and small-step operational semantics coincide. \( \square \)
5.5 Context lemma by Howe’s method

Proposition 5.4.2 (Equivalence) For any program $s$, $s \Downarrow v$ iff $s \gg v$ where $v$ is a value.

As in the case of CBN λ-calculus, for closed terms $s$ and $t$, we define $s \subseteq t$, read $s$ simulates $t$ applicatively, as the conjunction of a countable family of binary relations as follows:

- for any $s$ and $s'$, $s \subseteq_0 s'$.
- $s \subseteq_{k+1} s'$ just in case whenever $s \Downarrow \lambda x.p$ then $s' \Downarrow \lambda x.p'$ and for every value $v$, $p[v/x] \subseteq_k p'[v/x]$.

We then define $s \equiv s'$ to be $s \subseteq_k s'$ for all $k \in \omega$. The relation can be extended to λ-terms in general: for any $s$ and $t$, define $s \equiv t$ just in case $s_\sigma \subseteq t_\sigma$ for every value substitution $\sigma$.

Proposition 5.4.3 For any closed terms $s$ and $t$, the following are equivalent:

(i) $s \subseteq t$

(ii) for every finite sequence of closed terms $r_1, \ldots, r_n$, if $s \Downarrow r_1$ then $t \Downarrow r_n$

(ii) for every finite sequence of values $v_1, \ldots, v_n$, if $s \Downarrow v_1$ then $t \Downarrow v_n$.

5.5 Context lemma by Howe’s method

Context lemma is valid for CBN λ-calculus but the argument in the proof of Proposition 5.3.7 does not work for the CBN calculus. We shall present a proof using what is known as Howe’s method as an extended exercise.

A value substitution $\sigma$ is just a function $\sigma$ from variables to values. Suppose the variables occurring free in $s$ are $x_1, \ldots, x_n$ then

$$s_\sigma \overset{\text{def}}{=} s[\sigma(x_1)/x_1, \ldots, \sigma(x_n)/x_n].$$

Exercise 5.5.1 Prove the following:

(i) $\subseteq$ is a preorder.

(ii) For any $s$ and $t$ (which are not necessarily closed) and for any value $v$,

$$s \subseteq t \implies s[v/x] \subseteq t[v/x].$$

Definition 5.5.2 (Pre-simulation) Let $\mathcal{R}$ be the set of binary relations over the set of closed λ-terms. Define a function $F: \mathcal{R} \rightarrow \mathcal{R}$ by: for any $R \in \mathcal{R}$

$$F(R) \overset{\text{def}}{=} \{ (s, s') : \forall v.s \Downarrow v \implies [\exists v'.s' \Downarrow v' \& \forall t.(vt, vt') \in R] \}.$$

$F$ is a monotone function with respect to the inclusion ordering. A relation $R \in \mathcal{R}$ is said to be a pre-simulation just in case $R \subseteq F(R)$. Define $\preceq$ to be the maximal pre-simulation i.e.

$$\preceq \overset{\text{def}}{=} \bigcup_{R \subseteq F(R)} R.$$
Exercise 5.5.3 Prove the following:

(i) $F$ is a monotone function (with respect to the inclusion ordering).

(ii) $\subseteq$ is the same as $\sqsubseteq$.

Our aim is to prove the Context Lemma.

Definition 5.5.4 (Precongruence candidate) Define a binary relation $\subseteq$, called precongruence candidate, over the collection of all (not just closed) $\lambda$-terms by induction over the following rules:

- if $x \subseteq s$ then $x \leq s$
- if $s \leq t$ and $t \leq t'$ and $s t' \subseteq r$ then $st \leq r$
- if $s \leq t$ and $\lambda x.s \subseteq r$ then $\lambda x.s \leq r$.

Exercise 5.5.5 Prove the following:

(i) Whenever $s \leq t$ and $t \subseteq r$ then $s \leq r$.

(ii) $\subseteq$ is a precongruence i.e. whenever $s \leq t'$ and $t \leq t'$ then $st \leq s't'$, and whenever $s \leq s'$ then $\lambda x.s \leq \lambda x.s$.

Exercise 5.5.6 Prove that $\subseteq$ is reflexive. Hence deduce that $\sqsubseteq$ is contained in $\subseteq$.

Lemma 5.5.7 (Substitution Lemma) Prove that whenever $s \leq t$ and values $v \leq v'$ then

$$s[v/x] \leq s'[v'/x].$$

Exercise 5.5.8 For closed $s$ and $s'$, if $s \leq t'$ and $s \downarrow v$, then for some $v'$, $s' \downarrow v'$ and $v \leq v'$.

[Hint: Define a notion of “convergence in $n$ steps” $s \downarrow_n v$, and prove by induction over $n$, using the Substitution Lemma.]

Exercise 5.5.9 Prove that $\subseteq$ coincides with $\sqsubseteq$. Hence deduce the context lemma.

[Hint: To prove that $\subseteq$ is contained in $\sqsubseteq$, it suffices to show that $\subseteq$ is a pre-simulation (why?).]

Problems

Unless otherwise specified, assume $\downarrow$ and $\sqsubseteq$ as defined in the CBN $\lambda$-calculus in the following.

5.1 Formalize a small-step reduction for the CBN $\lambda$-calculus and prove that it is equivalent (in the sense of Proposition 5.4.2) to the big-step presentation.
5.2 Prove Proposition 5.2.2.

5.3 Prove Lemma 5.3.3.

5.4 (i) Show that \( \Omega \equiv (\lambda x.xx)(\lambda x.xx) \) is a bottom element and \( yk \) a top element with respect to applicative simulation.

(ii) A classification of closed \( \lambda \)-terms.

For any (closed) \( \lambda \)-term \( s \), say that \( s \) has order 0 just in case \( s \) is not \( \beta \)-convertible to an abstraction. Suppose \( s \) is \( \beta \)-convertible to an abstraction. For \( n \geq 1 \), say that \( s \) has order \( n \) if \( n \) is largest \( k \) such that for some \( p \), \( \lambda \beta \vdash s = \lambda x_1 \cdots x_k p \). We say that \( s \) has order \( \infty \) just in case for no \( n \in \omega \) is \( s \) of order \( n \). Observe that every closed \( \lambda \)-term has a unique order.

Show that a \( \lambda \)-term is a bottom element w.r.t. applicative simulation iff it is of order 0; and top element iff it is of order \( \infty \).

5.5 \( \lambda \) is a \( \lambda \)-theory

(i) Is it true that if \( \lambda \beta \vdash s = t \) then \( s \sim t \)? Is it true that if \( s = s' \) and \( t = t' \) in \( \lambda \beta \) and if \( s \not\subseteq t \) then \( s' \not\subseteq t' \)?

(ii) Prove that \( \lambda \) is a \( \lambda \)-theory.

(iii) Show that the axiom \((\eta)\) is not valid in \( \lambda \). Rather a weaker version, called \textit{conditional-\( \eta \)},

\[
s \downarrow \implies \lambda x. sx = s
\]

is valid, where we interpret \( s \downarrow \) to mean “\( s \) converges”.

5.6 (i) Show that \( xx \in x(\lambda y.xy) \) in the CBN \( \lambda \)-calculus. Is it true in the CBV \( \lambda \)-calculus?

(ii) Are there \( \beta \eta \)-inequivalent \( \beta \)-normal forms that are equal in \( \lambda \)?

(iii) The answer to (ii) is yes if we relax the \( \beta \)-normality requirement, or if the pair are only required to be \( \beta \)-inequivalent. Why?

5.7 Convergence testing ★

(i) A convergence test is a closed \( \lambda \)-term \( c \) such that \( c \downarrow \), and for any \( s \in \Lambda^0 \)

\[
\begin{align*}
    s \downarrow & \implies cs \downarrow \lambda x.x \\
    s \uparrow & \implies cs \uparrow.
\end{align*}
\]

Show that there is no convergence test in the CBN \( \lambda \)-calculus.

(ii) Let \( \top \) be any order-\( \infty \) term, and \( \bot \) any order-0 term. Let \( p \equiv \lambda x.x(\lambda y.x \top \bot) \top \) and \( q \equiv \lambda x.x(\top \bot) \top \). Prove that \( p \sim q \).

(iii) Let \( p' \) and \( q' \) be obtained from \( p \) and \( q \) respectively by replacing \( \top \) in them by \( \lambda y.\bot \). Prove that we still have \( p' \sim q' \).

(iv) Show that there is a convergence test in the CBV \( \lambda \)-calculus.

5.8 Describe, and characterize if possible, the least and greatest terms w.r.t. \( \in \) in the CBV \( \lambda \)-calculus.

5.9 Use Howe’s method to prove that \( \in \) in the CBN \( \lambda \)-calculus is a precongruence.
6 (Very) Basic Recursion Theory

In this section we show the Turing completeness of the call-by-value \(\lambda\)-calculus (viewed as a minimal programming language) and the undecidability of \(\beta\)-convertibility.

In the following \(s \downarrow v\) shall mean the evaluation of program \(s\) to value \(v\) in the call-by-value \(\lambda\)-calculus; and \(s \gg s'\) the reflexive, transitive closure of the one-step call-by-value reduction. Note that

\[
s \downarrow v \iff s \gg v \& v \text{ is a value.}
\]

6.1 Numerals

The salient feature of Scott numerals is the simplicity of the definition of predecessor. (Compare it with Church numerals.)

**Definition 6.1.1**

\[
\begin{align*}
\%0 & \overset{\text{def}}{=} k \\
\%n + 1 & \overset{\text{def}}{=} \lambda xy.\%n y \\
\text{succ} & \overset{\text{def}}{=} \lambda nxy.yn \\
\text{pred} & \overset{\text{def}}{=} \lambda p.p\theta \\
\text{case} & \overset{\text{def}}{=} \lambda xyz.xyz
\end{align*}
\]

where \(\theta\) is any closed term and \(i\) the identity.

Note that for any values \(f\) and \(g\)

\[
\text{case} \%n f g \gg \begin{cases} 
  f & \text{if } n \text{ is 0} \\
  g(\%n - 1) & \text{otherwise.}
\end{cases}
\]

6.2 Strong definability

A function can be defined by specifying its graph. We associate to every partial recursive function a CBV \(\lambda\)-calculus program that defines it i.e. the extensional behaviour of the program coincides with the graph of the function. Note that the program gives a way of computing it.

**Definition 6.2.1** We say that a partial function \(\phi : \mathbb{N}^m \rightarrow \mathbb{N}\) is strongly \(\lambda_v\)-definable by a program \(f\) just in case for every \(m\)-tuple \(n_1, \ldots, n_m\) of natural numbers,

\[
\begin{align*}
\phi(\%n) & \uparrow \iff f(\%n_1 \ldots \%n_m) \uparrow \\
\phi(\%n) & = l \iff f(\%n_1 \ldots \%n_m) \downarrow \%l
\end{align*}
\]

where “\(\ldots \uparrow\)” means that “\(\ldots\) is undefined”.

**Theorem 6.2.2 (Turing completeness)** A partial function \(\mathbb{N}^m \rightarrow \mathbb{N}\) is partial recursive if and only if it is strongly \(\lambda_v\)-definable.
Notation We write \( \phi \triangleright f \) to mean “\( \phi \) is strongly \( \lambda_v \)-definable by \( f \)”.

Lemma 6.2.3 \( st_1 \cdots t_n \downarrow v \) if and only if for each \( i, t_i \downarrow u_i \) and \( su_1 \cdots u_n \downarrow v \). \( \square \)

Exercise 6.2.4 (i) Prove the lemma.

(ii) The lemma is not true for CBN \( \lambda \)-calculus. Give a counterexample.

Proof of the theorem

It should be evident that a program of CBV \( \lambda \)-calculus defining a numeric function gives an algorithm for computing it. The direction “\( \Rightarrow \)” can be shown by appealing to Church’s Thesis\(^1\). It then remains to prove “\( \Leftarrow \)”.

Projection
\( \text{proj}_i^m \) is \( \lambda x_1 \cdots x_m . x_i \).

Composition
Suppose \( \chi \triangleright g \) and \( \psi_i \triangleright f_i \) and \( \phi(\overline{n}) = \chi(\psi_1(\overline{n})), \cdots, \psi_m(\overline{n})) \). Now

\[
\phi(\overline{n}) = p \quad \text{iff} \quad \text{for each } i, \psi_i(\overline{n}) = p_i \text{ and } \chi(p_1, \cdots, p_m) = p
\]

\[
\text{iff} \quad f_i(\overline{n}) \downarrow p_i \text{ for each } i \text{ and } g^\overline{n} \downarrow p \quad \text{by Lemma 6.2.3}
\]

\[
\text{iff} \quad (\lambda \overline{x} . g(f_1 \overline{x}) \cdots (f_m \overline{x}))^\overline{n} \downarrow p
\]

Also

\[
\phi(\overline{n}) \uparrow \quad \text{iff} \quad \text{for some } i, \psi_i(\overline{n}) \uparrow \text{ or for each } i, \psi_i(\overline{n}) = p_i \text{ and } \chi(\overline{n}) \uparrow
\]

\[
\text{iff} \quad \text{for some } i, f_i(\overline{n}) \uparrow \text{ or for each } i, f_i(\overline{n}) \downarrow p_i \text{ and } g^\overline{n} \uparrow
\]

\[
\text{iff} \quad (\lambda \overline{x} . g(f_1 \overline{x}) \cdots (f_m \overline{x}))^\overline{n} \uparrow
\]

Primitive recursion
Suppose

\[
\phi(0, \overline{y}) \overset{\text{def}}{=} \psi(\overline{y})
\]

\[
\phi(k + 1, \overline{y}) \overset{\text{def}}{=} \chi(\phi(k, \overline{y}), k, \overline{y})
\]

where \( \psi \triangleright g \) and \( \chi \triangleright h \). Define \( B \equiv \lambda xy.y(\lambda z.xxyz) \). Note for any value \( v \)

\[
BBv \quad > \quad (\lambda y.y(\lambda z.BBvz))v
\]

\[
> \quad v(\lambda z.BBvz).
\]

\(^1\)By Church’s Thesis, we shall mean the assertion that the \textit{effectively computable} (partial) numeric functions are exactly the (partial) recursive functions.
Now set
\[ \Theta \overset{\text{def}}{=} BB \]
\[ v \overset{\text{def}}{=} \lambda z x y . \text{case } x(g y)(\lambda \alpha. h(\alpha y)) \]
\[ R_\phi \overset{\text{def}}{=} \Theta v \]

Take \( \overrightarrow{a}, \overrightarrow{b} \) to be values, and set \( f \) to be \( \Theta v \). Then
\[ f \overrightarrow{a} \overrightarrow{b} \gg v(\lambda z.\Theta v z) \overrightarrow{a} \overrightarrow{b} \]
\[ \gg \text{case } a(\overrightarrow{b})((\lambda \alpha. h((\lambda z.\Theta v z)\alpha) \overrightarrow{a} \overrightarrow{b})) \]

- if \( a \) is \( \overrightarrow{0} \) then \( f^{\overrightarrow{0}} \overrightarrow{b} \gg p \) provided \( g \overrightarrow{b} \downarrow p \)
- if \( a \) is \( \overrightarrow{n + 1} \) then
\[ f^{\overrightarrow{n + 1}} \overrightarrow{b} \gg (\lambda \alpha. h((\lambda z.\Theta v z)\alpha) \overrightarrow{b})^{\overrightarrow{n + 1}} \]
\[ > h((\lambda z.\Theta v z)^{\overrightarrow{n + 1}} \overrightarrow{b})^{\overrightarrow{n + 1}} \overrightarrow{b} \]
\[ > h((\Theta v)^{\overrightarrow{n + 1}} \overrightarrow{b})^{\overrightarrow{n + 1}} \overrightarrow{b} . \]

\textit{Minimalization}

Suppose \( \psi \triangleright g \). Define \( \phi(\overrightarrow{y}) \) to be \( \mu x. \psi(x, \overrightarrow{y}) \). Set
\[ v \overset{\text{def}}{=} \lambda z x y . \text{case } (g x y) x((\lambda z.(\text{succ } x) y)) \]
\[ h \overset{\text{def}}{=} \Theta v . \]

\textbf{Claim:} For values \( \overrightarrow{b} \),
\[ h^{\overrightarrow{n}} \overrightarrow{b} \gg \begin{cases} 
\overrightarrow{n} & \text{if } g^{\overrightarrow{n}} \overrightarrow{b} \downarrow \overrightarrow{0} \\
 h(\text{succ } \overrightarrow{n}) \overrightarrow{b} & \text{otherwise if } g^{\overrightarrow{n}} \overrightarrow{b} \downarrow \overrightarrow{m + 1} \text{ for some } m. 
\end{cases} \]

Now put \( f \overset{\text{def}}{=} h^{\overrightarrow{0}} . \]

\textit{Church numerals} are defined as follows:
\[ n \overset{\text{def}}{=} \lambda f x . f(\cdots(f x)\cdots) \]

Think of the Church numeral \( n \) as the procedure that takes a function-input and an argument-input, and applies the function \( n \)-times to the argument.
6.3 Undecidability of $\beta$-convertibility

Fix an effective Gödel numbering $g$ of $\lambda$-terms i.e. a (bijective) function $g : \Lambda \rightarrow \mathbb{N}$ that is computable. It should be clear that we have the following:

**Fact 6.3.1**

(i) There is a total recursive function $\tau$ such that for any $\lambda$-terms $s$ and $t$, $\tau(g(s), g(t)) = g(st)$.

(ii) There is a total recursive function $\nu$ such that for any natural number $n$, $\nu(n) = g(n)$. □

**Notation** In the following we shall write

$$[s] \overset{\text{def}}{=} g(s)$$

for each $s \in \Lambda$ i.e. $[s]$ is the Church numeral of the Gödel numbering of $s$.

**Lemma 6.3.2** From the preceding fact it follows that there are $\lambda$-terms $p$ and $q$ such that

$$p[s][t] = [st]$$
$$q[n] = [n]$$

for any $\lambda$-terms $s$ and $t$, and for any $n \in \mathbb{N}$. □

**Theorem 6.3.3 (Scott-Curry)** Let $A$ and $B$ be two collections of $\lambda$-terms that are closed under $\beta$-convertibility. There is no $\lambda$-term $F$ such that for each $n$, $F[\underline{n}] = \underline{0}$ or $\underline{1}$, and satisfying

$$F[u] = \begin{cases} 
  \underline{1} & \text{if } u \in A \\
  \underline{0} & \text{if } u \in B 
\end{cases}$$

Note that the $=$ is that of the formal system $\lambda\beta$.

**Proof** W.l.o.g. assume that $A$ and $B$ are disjoint. Suppose, for a contradiction, such an $F$ exists.

**Claim** Fix some $A \in A$ and $B \in B$. There is a $J$ such that

$$\begin{cases} 
  F[J] = \underline{1} & \Rightarrow J = B \\
  F[J] = \underline{0} & \Rightarrow J = A. 
\end{cases}$$

The Claim gives a contradiction. (Convince yourself that this is so.)

**Construction of $J$** Let $D$ be $\lambda xyz.z(ky)x$. Then for any $A$ and $B$, by a simple calculation, we see that

$$DAB\underline{1} = B$$
$$DAB\underline{0} = A.$$
Let \( H \equiv \lambda y. DAB(F(p_y(q_y))) \) and write \( H[H] \) as \( J \). Now
\[
J \equiv H[H] \\
= DAB(F(p[H](q[H]))) \quad \text{by Lemma 6.3.2} \\
= DAB(F(p[H][H]))) \quad \text{by Lemma 6.3.2} \\
= DAB(F[J]).
\]

It follows that \( J \) thus defined satisfies the two implications in the Claim. \( \square \)

“\( \beta \) is decidable” (by Church’s Thesis) is the statement that there is \( \lambda \)-term \( G \) such that for any \( s, t \in \Lambda \),
\[
G[s][t] = \begin{cases} 
1 & \text{if } s = t \\
0 & \text{otherwise}. 
\end{cases}
\]

**Corollary 6.3.4** \( =_\beta \) is undecidable.

**Proof** Suppose not. Take any \( \lambda \)-term, say, \( s \). Let \( A \) be the \( =_\beta \)-equivalence class of \( s \) and \( B \) be \( \Lambda - A \). Write \( F = G[s] \). Then \( F \) violates the theorem. \( \square \)

**Theorem 6.3.5 (Second Fixed-Point Theorem)** For any \( F \), there exists an \( X \) such that
\[
F[X] = X.
\]

\( \square \)

---

**Problems**

6.1 (i) Give the respective \( \lambda \)-terms that define the successor and predecessor (hard!) functions, and definition by cases (boolean conditional) for Church numerals.

(ii) Prove that cbv \( \lambda \)-calculus is Turing complete relative to Church numerals.

(iii) Prove that cbn \( \lambda \)-calculus is Turing complete.

6.2 Give an effective **Gödel numbering** of \( \lambda \)-terms i.e. a (bijective) function \( g : \Lambda \to \mathbb{N} \) that is computable.

[Your encoding should be invariant over terms that are \( \alpha \)-convertible. Hint: use **de Bruijn notation** to represent \( \lambda \)-terms.]

6.3 Prove the following results:

(i) There is a total recursive function \( \tau \) such that for any \( \lambda \)-terms \( s \) and \( t \), \( \tau(g(s), g(t)) = g(st) \).
(ii) There is a total recursive function \( \nu \) such that for any natural number \( n \), \( \nu(n) = g(n) \).

6.4  (i) Why is the Claim in the proof of the Undecidability Theorem sufficient to force a contradiction?

(ii) Prove the Second Fixed-point Theorem. [Hint: Use the trick in the construction of \( J \) (in the proof of the undecidability Theorem) to construct the required \( X \).

6.5 Prove that \( \{ s : s \text{ has a } \beta\text{-nf} \} \) is an r.e. set that is not recursive.

B Sample examination questions

B.1 Prove that the $\lambda$-calculus is consistent.
[You should state what you mean by consistency carefully.]

B.2 (i) State and prove a result that relates the Church-Rosser property to the consistency of a formal theory of equations over a set of terms.

(ii) Prove that the formal theory $\lambda\beta$ is consistent.

(iii) Is the formal theory obtained from $\lambda\beta$ by augmenting it by $s = k$ consistent? Justify your result.

B.3 (i) State the Church-Rosser Theorem for $\beta$-reduction. Explain briefly why it is an important result in $\lambda$-calculus.

(ii) What is a fixed point combinator? Set $g \equiv \lambda y f. f(yf)$. Prove that any $\lambda$-term $s$ is a fixed point combinator if and only if $s$ is a fixed point of $g$.

(iii) Show that if $y$ is a fixed point combinator, then so is $yg$. Hence, or otherwise, show that there are infinitely many ($\beta$-inequivalent) fixed point combinators.

B.4 (i) Give a Gödel numbering on $\lambda$-terms i.e. an effectively given (computable) injective map $\# : A \longrightarrow N$.

(ii) Use the Second Fixed Point Theorem to prove the Scott-Curry Theorem: Let $A$ and $B$ be two collections of $\lambda$-terms that are closed under $\beta$-convertibility. There is no $\lambda$-term $p$ such that for each natural number $n$, $p_n = 0$ or $1$, and

$$ p^\upharpoonright u \downarrow = \begin{cases} 1 & \text{if } u \in A \\ 0 & \text{if } u \in B \end{cases} $$

where $=$ is the equational theory of the formal system $\lambda\beta$.

(iii) Hence, or otherwise, prove that the formal equational theory $\lambda\beta$ is undecidable.

B.5 “The $\lambda$-calculus is Turing complete.” Discuss.
[You should state carefully any relevant definition and theorem, and give a proof of a major theorem in developing your argument.]

B.6 (i) Define Scott numerals and Church numerals.

(ii) Give a Gödel numbering on $\lambda$-terms i.e. an effectively given (computable) injective map $\# : A \longrightarrow N$. 
(iii) For each \( \lambda \)-term \( s \), define \( \tilde{s} \) where \( \tilde{s} = \#s \) where \( \# \) is the \( n \)-th Church numeral. Prove the Second Fixed Point Theorem: for any \( t \in \Lambda \), there is a \( u \in \Lambda \) such that \( t^\uparrow u^\uparrow = u \).

\textbf{B.7} (i) Define applicative simulation \( \sqsubseteq \) for the call-by-name (CBN) \( \lambda \)-calculus.

(ii) Prove that applicative simulation is the maximal fixed point of a monotone function \( F : \mathcal{R} \to \mathcal{R} \) where \( \mathcal{R} \) is the set of binary relations over the set \( \Lambda^o \) of closed \( \lambda \)-terms ordered by set inclusion.

(iii) State and prove a characterization result for \( \sqsubseteq \).

(iv) Is it true that \( \lambda x. s x \sqsubseteq s \) for all \( s \in \Lambda^o \)?

\textbf{B.8} Let \( s, s', t \) and \( t' \) range over closed \( \lambda \)-terms.

(i) Define applicative simulation \( \sqsubseteq \) for the call-by-name (CBN) \( \lambda \)-calculus, and give (without proof) a characterization of it solely in terms of the convergence predicate \( \neg \downarrow \).

(ii) Prove that \( \lambda \beta \vdash s = \lambda x. p \) if and only if \( s \downarrow \). Deduce that \( s = s' \) and \( s \downarrow \) imply \( s' \downarrow \).

(iii) Hence, or otherwise, prove that if \( \lambda \beta \vdash s = s' \) then \( s \sim s' \) (i.e., \( s \sqsubseteq s' \) and \( s' \sqsubseteq s \)).

(iv) Recall that a \( \lambda \)-theory is a consistent extension of \( \lambda \beta \) that is closed under provability. Deduce that \( \lambda \ell = \{ s = t : s \sim t \} \) is a \( \lambda \)-theory.

\textbf{B.9} (i) Define the call-by-name \( \lambda \)-calculus, and give its operational semantics in terms of a Martin-Löf style evaluation relation and a Plotkin-style transition relation. Show that the two are equivalent.

(ii) What is the Context Lemma? Give a careful proof in the case of the call-by-name \( \lambda \)-calculus.

\textbf{B.10} Let \( \mathcal{L} \) be the (first-order) language with constant symbols \( k, s \) and a binary function symbol for application.

(i) Define an operation \( \hat{\lambda}x. - : \mathcal{L} \to \mathcal{L} \) parametrized by variables \( x \) of \( \mathcal{L} \): for each \( x \), there is a map \( a \mapsto \hat{\lambda}x.a \), where \( a \in \mathcal{L} \) and where \( \hat{\lambda}x.a \) is defined by recursion as:

\begin{align*}
\hat{\lambda}x.x & \overset{\text{def}}{=} \text{skk} \\
\hat{\lambda}x.a & \overset{\text{def}}{=} k a \quad \text{if } a \text{ is a variable } \not\in x \text{ or } a \in \{ s, k \} \\
\hat{\lambda}x.ab & \overset{\text{def}}{=} s(\hat{\lambda}x.a)(\hat{\lambda}x.b) \quad \text{if the previous cases do not apply}
\end{align*}

Prove that \( C_0 \vdash \forall x. (\hat{\lambda}x.a)x = a \). Hence prove that \( C_0 \vdash (\hat{\lambda}x.a)b = a[b/x] \) for all \( b \in \mathcal{L} \).

(ii) What is a combinatory algebra? Define combinatory completeness (of an applicative structure).

(iii) Using (i), or some other abstraction algorithm, prove that an applicative structure is combinatory complete if and only if it can be given the structure of a combinatory algebra.
B.11 “The λ-calculus and Combinatory Logic are essentially equivalent.” Discuss.

B.12 (i) Define the call-by-value (CBV) λ-calculus and give its operational semantics in terms of both the Martin-Löf style evaluation (big-step) relation \( \downarrow \) and Plotkin-style transition (small-step) relation \( \triangleright \).

(ii) Prove that the big-step and small-step reduction relations are equivalent i.e. for any \( s, v \in \Lambda^o \)

\[
s \downarrow v \iff s \triangleright v \land v \not\triangleright
\]

where \( \triangleright \) is the reflexive transitive closure of \( \triangleright \) and \( v \not\triangleright \) means there is no \( u \in \Lambda \) for which \( v \triangleright u \) holds.

(iii) Say that convergence testing is definable in a λ-calculus endowed with an evaluation relation \( \downarrow \) if there is a term \( c \in \Lambda^o \) such that for any \( s \in \Lambda^o \)

\[
\begin{align*}
s \downarrow &\implies cs \downarrow \lambda x.x \\
s \uparrow &\implies cs \uparrow.
\end{align*}
\]

Is convergence testing definable in CBV λ-calculus?

B.13 (i) Define the syntax of Scott’s language \( \text{PCF} \) and give its operational semantics in terms of either a small-step or a big-step reduction relation.

(ii) State and prove the Context Lemma for \( \text{PCF} \).

B.14 State and prove the Weak Adequacy Theorem for Scott’s language \( \text{PCF} \).
C  Lambda Calculus Mini-projects

University of Oxford, MSc (Maths & FoCS)

Lambda Calculus

Mini-project 1: Context lemma for the call-by-value λ-calculus

Michaelmas 1995

Instructions to candidates: The following series of problems take you through a proof of the context lemma for the call-by-value λ-calculus. Your project should take the form of a mathematical report on your progress in solving the problems.

We let p, r, s and t range over λ-terms. Programs of Plotkin’s call-by-value λ-calculus are closed λ-terms, and values, ranged over by u and v, are closed abstractions. Evaluation is defined by induction over the following rules: for programs λx.p, s and t

\[
\begin{align*}
\lambda x.p & \Downarrow \lambda x.p \\
\frac{s \Downarrow \lambda x.p \quad t \Downarrow u \quad p[u/x] \Downarrow v}{st \Downarrow v}
\end{align*}
\]

We read \( s \Downarrow v \) as “the program \( s \) converges or evaluates to value \( v \)”, and write \( s \Downarrow \) to mean \( s \Downarrow v \) for some value \( v \). Recall that \( \Downarrow \) is deterministic i.e. \( \Downarrow \) defines a partial function.

Definition 1 (Applicative simulation)  
(i) For closed \( s \) and \( t \), \( s \) is said to simulate \( t \) applicatively, written \( s \triangleleft t \), just in case for every finite (possibly empty) sequence of closed terms \( r_1, \ldots, r_n \), if \( s r_1 \Downarrow \) then \( t r_n \Downarrow \).

(ii) Applicative simulation can be extended to a relation over λ-terms in general: for any \( s \) and \( t \), define \( s \triangleleft t \) just in case \( s_{\sigma} \triangleleft t_{\sigma} \) for every value substitution \( \sigma \).

A value substitution \( \sigma \) is just a function \( \sigma \) from variables to values. Suppose the variables occurring free in \( s \) are \( x_1, \ldots, x_n \) then

\[
s_{\sigma} \overset{\text{def}}{=} s[\sigma(x_1)/x_1, \ldots, \sigma(x_n)/x_n].
\]

Problem 1 Prove the following:

(i) \( \triangleleft \) is a preorder.

(ii) For any \( s \) and \( t \) (which are not necessarily closed) and for any value \( v \),

\[
s \triangleleft t \implies s[v/x] \triangleleft t[v/x].
\]

\[\square\]

Definition 2 (Pre-simulation) Let \( R \) be the set of binary relations over the set of closed λ-terms. Define a function \( F : R \to R \) by: for any \( R \in R \)

\[
F(R) \overset{\text{def}}{=} \{ (s,s') : \forall v. s \Downarrow v \implies [\exists v'. s' \Downarrow v' \& \forall t. (vt,v't) \in R] \}.
\]
F is a monotone function with respect to the inclusion ordering. A relation $R \in \mathcal{R}$ is said to be a pre-simulation just in case $R \subseteq F(R)$. Define $\preceq$ to be the maximal pre-simulation i.e.

$$\preceq \overset{\text{def}}{=} \bigcup_{R \subseteq F(R)} R.$$

**Problem 2** Prove the following:

(i) $F$ is a monotone function (with respect to the inclusion ordering).

(ii) $\preceq$ is the same as $\subseteq$. □

**Definition 3 (Observational preorder)** For closed $s$ and $t$, $s$ is said to approximate $t$ observationally just in case for any closed context $C[X]$ whenever $C[s] \Downarrow$ then $C[t] \Downarrow$.

**Context lemma** is said to be valid for call-by-value $\lambda$-calculus if applicative simulation (restricted to closed terms) coincides with observational preorder. Our aim is to prove the Context Lemma.

**Definition 4 (Precongruence candidate)** Define a binary relation $\preceq$, called precongruence candidate, over the collection of all (not just closed) $\lambda$-terms by induction over the following rules:

- if $x \subseteq s$ then $x \leq s$
- if $s \leq s'$ and $t \leq t'$ and $s't' \subseteq r$ then $st \leq r$
- if $s \leq s'$ and $\lambda x.s' \subseteq r$ then $\lambda x.s \leq r$.

**Problem 3** Prove the following:

(i) Whenever $s \leq t$ and $t \subseteq r$ then $s \leq r$.

(ii) $\preceq$ is a precongruence i.e. whenever $s \leq s'$ and $t \leq t'$ then $st \leq s't'$, and whenever $s \leq s'$ then $\lambda x.s \leq \lambda x.s'$. □

**Problem 4** Prove that $\preceq$ is reflexive. Hence deduce that $\subseteq$ is contained in $\preceq$. □

**Problem 5 (Substitution Lemma)** Prove that whenever $s \leq s'$ and values $v \leq v'$ then

$$s[v/x] \leq s'[v'/x].$$

□

**Problem 6** For closed $s$ and $s'$, if $s \leq s'$ and $s \Downarrow v$, then for some $v'$, $s' \Downarrow v'$ and $v \leq v'$.

[Hint: Define a notion of “convergence in $n$ steps” $s \downarrow_n v$, and prove by induction over $n$, using the Substitution Lemma.]

**Problem 7** Prove that $\preceq$ coincides with $\subseteq$. Hence deduce the context lemma.

[Hint: To prove that $\preceq$ is contained in $\subseteq$, it suffices to show that $\preceq$ is a pre-simulation (why?).]
Instructions to candidates: Your project should take the form of a mathematical report on your progress in solving problems in both Parts I and II.

I. An adequacy theorem

Let $D$ be a cpo. A subset $X$ of $D$ is said to be inductive if it is downward closed and, for every $\omega$-increasing chain $\langle d_i \rangle_{i \in \omega} \subseteq X$, the least upper bound (lub) $\bigsqcup d_i$ is an element of $X$.

Let $r, s$ and $t$ range over terms of PCF and $u$ and $v$ over values.

Definition 1 For each PCF-type $A$, for each $d$ in the standard domain $D_A$ of type $A$, and for each closed term $s$ of type $A$, define $d \triangleleft_A s$ if

- $d = \bot$ or
- $s \downarrow v$ and $d \triangleleft_A v$ where
  - $f \triangleleft_B C u$ if for each $g \in D_B$ and for each closed term $t$ of type $B$, $g \triangleleft_B t \implies f \triangleleft_B C u t$
  - $t \triangleleft_o t$, $f \triangleleft_o f$
  - $n \triangleleft_i n$.

Problem 1 Prove that for each type $A$, and for each closed term $s$ of type $A$, the set

$$\{ d \in D_A : d \triangleleft_A s \}$$

is inductive.

Problem 2 Suppose $x_1 : A_1, \ldots, x_n : A_n \vdash s : A$ for $n \geq 0$. For each $1 \leq i \leq n$, for each $d_i \in D_{A_i}$, and for each closed term $t_i$ of type $A_i$ such that $d_i \triangleleft_{A_i} t_i$, prove that

$$[ s ]_{x_1 \mapsto d_1, \ldots, x_n \mapsto d_n} \triangleleft_A s[t_1/x_1, \ldots, t_n/x_n].$$

Problem 3 (Adequacy theorem) (i) Prove that for each closed term $s$ of program type (i.e. $o$ or $i$), $[ s ] \neq \bot$ if and only if $s \downarrow v$ for some $v$.

(ii) Is the result valid for closed terms of higher type? Justify your answer.
II. A combinatory logic version of PCF

The aim is to define a combinatory logic version of PCF called $\text{PCF}^{cl}$. The type structure and the constants (numerals, booleans, successor, predecessor, test-for-zero, conditional and fixed-point constants) should have the same sense as those of the standard PCF.

Problem 4 Define the syntax of $\text{PCF}^{cl}$ and give the formal system that defines typing sequents of the form $x_{A_1}, \ldots, x_{A_n} \vdash s : A$ which means that the term $s$ has type $A$ in the context where (free) variables $x_1, \ldots, x_n$ have types $A_1, \ldots, A_n$ respectively.

Problem 5 Define either a “small-step” (Plotkin-style transition relation $s \rightarrow s'$) or a “big-step” (Martin-Löf style evaluation relation $s \Downarrow v$) call-by-name operational semantics for $\text{PCF}^{cl}$. What properties can you establish for the semantics?

Problem 6 Examine the relationship between $\text{PCF}^{cl}$ and PCF. To what extent do they agree?
Lambda Calculus

Mini-project 1: Call-by-name λ-calculus and convergence testing

Michaelmas 1996

Instructions to candidates: Answer as many problems as you can.

λc-terms, ranged over by s, t, etc., are defined as follows:

\[ s ::= x \mid c \mid (st) \mid (\lambda x.s) \]

where \( x \) ranges over a denumerable collection of variables, and \( c \) is a constant, known as convergence test. Write \( \Lambda(c) \) (respectively \( \Lambda(c)^0 \)) for the collection of λc-terms (respectively closed λc-terms). Programs are closed terms; and values, ranged over by \( u, v, v' \), etc., are closed abstractions and \( c \). Evaluation is defined by induction over the following rules:

\[
\begin{align*}
\lambda x. p & \Downarrow \lambda x. p & c \Downarrow c & s \Downarrow \lambda x. p \quad p[t/x] \Downarrow v \quad s \Downarrow c \quad t \Downarrow v \\
     & \Downarrow s \quad st \Downarrow v & \Downarrow s \quad c \quad t \quad \Downarrow i \\
\end{align*}
\]

where \( i = \lambda y.y \). We read \( s \Downarrow v \) as “program \( s \) converges or evaluates to value \( v \)”, and write \( s\Downarrow \) to mean \( s \Downarrow v \) for some value \( v \).

**Problem 1**  (i) Give a Plotkin-style transition relation \( > \subseteq \Lambda(c)^0 \times \Lambda(c)^0 \) that is equivalent to \( \Downarrow \) in the sense that for any program \( s \), and for any value \( v \),

\[ s \Downarrow v \iff s \gg v \land v \neq \]

where \( \gg \) is the reflexive, transitive closure of \( > \), and \( t \neq \) means \( -[\exists t'.t > t'] \).

(ii) A transition relation \( > \) is said to be characterized by a set \( E \) of evaluation contexts (each of which must have exactly one “hole”) and a set \( R \) of redex rules just in case for any \( s, s' \), \( s > s' \) iff there is a unique \( E \in E \) such that \( s \equiv E[\theta], s' \equiv E[\theta'] \) and \( \theta > \theta' \) is an instance of a redex rule in \( R \).

Set \( R \) to be the following redex rules:

\[
(\beta) \quad (\lambda x.p)t > p[t/x] \\
(c) \quad c(\lambda x.p) > i.
\]

Define the set \( E \) of evaluation contexts that, together with \( R \), characterize the transition relation \( > \) in (i). Justify your answer.

**Problem 2** Define the one-step reduction relation \( \rightarrow \) (as a binary relation over \( \Lambda(c) \)) by induction over the following rules:

\[
(\lambda x.p)t \rightarrow p[t/x] \quad c(\lambda x.p) \rightarrow i \quad s \rightarrow s' \quad ts \rightarrow ts' \quad st \rightarrow st' \quad \lambda x.s \rightarrow \lambda x.s'
\]

Prove that \( \rightarrow \) is Church-Rosser.

[Hint: Define an appropriate “parallel reduction” relation that satisfies the diamond property.]
Problem 3  (i) Show that convergence testing is not definable in call-by-name λ-calculus (as defined in section 5 of your notes). That is to say, writing \( \downarrow \) as the evaluation relation of call-by-name λ-calculus, show that there is no closed λ-term \( c \) such that \( c \downarrow \), and for any \( s \in \Lambda^o \)

\[
\begin{align*}
\text{if } s \downarrow & \implies cs \downarrow \\
\text{if } s \uparrow & \implies cs \uparrow
\end{align*}
\]

where \( s \uparrow \) means \( \neg \exists v. s \downarrow v \).

(ii) Let \( \top \) be any order-∞ term, and \( \bot \) any order-0 term. Let \( p \equiv \lambda x. x(\lambda y. x \top \bot) \top \) and \( q \equiv \lambda x. x(\top \bot) \top \). Prove that \( p \sim q \) where \( \sim \) is applicative bisimilarity i.e. \( p \not\sim q \) and \( q \not\sim p \).

(iii) Let \( p' \) and \( q' \) be obtained from \( p \) and \( q \) respectively by replacing \( \top \) in them by \( \lambda y. \bot \). Prove that \( p' \sim q' \).

(iv) Is it still the case that \( p \sim q \) in λ-calculus with convergence testing (where \( \sim \) is applicative bisimilarity of the augmented calculus)? No proof is required.

Instructions to candidates: Answer as many problems as you can.

Problem 1 Show that the following conditions on a cpo (i.e. a poset that has a least element and such that every directed subset has a LUB) are equivalent:

(1) Any two points that are bounded above have a LUB.
(2) Every subset that is bounded above has a LUB.
(3) Every non-empty subset has a GLB.

A cpo is said to be consistently complete just in case condition (2) (and hence, equivalently, (1) or (3)) is satisfied.

A consistently complete cpo $D$ is said to be distributive just in case for any $x, y, z \in D$, if $y$ and $z$ are bounded above, then

$$x \land (y \lor z) = (x \land y) \lor (x \land z).$$

A Scott domain is a consistently complete, $\omega$-algebraic cpo. A dI-domain is a distributive Scott domain that satisfies the following axiom:

(I): Every compact element dominates only finitely many elements.

An element $x$ of a cpo $D$ is a prime just in case for any subset $X \subseteq D$ that has a LUB,

$$x \leq \bigsqcup X \implies \exists y \in X, x \leq y.$$

A cpo is prime algebraic if every element $x$ is the LUB of the set of prime elements that are dominated by $x$.

Problem 2  (i) Prove that a Scott domain $D$ is distributive if and only if for all $x, y, z \in D$, if $\{x, y, z\}$ is bounded above then

$$x \land (y \lor z) = (x \land y) \lor (x \land z).$$

(ii) Suppose that a subset $X = X_1 \cup X_2$ of a Scott domain is bounded above then

$$\bigsqcup X = (\bigsqcup X_1) \lor (\bigsqcup X_2).$$

(iii) An element $y$ of a cpo is said to cover $x$ just in case $x < y$, and for any $z$, whenever $x \leq z \leq y$ then $z = y$ or $z = x$. Prove that in a dI-domain, prime elements are precisely those compact elements that cover exactly one element.
(iv) Using (i) to (iii), or otherwise, prove that in a Scott domain $D$ that satisfies the axiom (I),
distributivity is equivalent to prime algebraicity.

Let $D$ and $E$ be cpos such that any two elements that are bounded above have a glb. A function $f : D \to E$ is said to be **stable** just in case it is continuous, and for any two elements $x$ and $y$ that are bounded above,

$$f(x \wedge y) = f(x) \wedge f(y).$$

Let $f$ and $g$ be functions from $D$ to $E$. $f$ is said to be less than $g$ **extensionally** just in case

$$f \leqslant^\text{ext} g \overset{\text{def}}{=} \forall x \in D. f(x) \leq g(x).$$

$f$ is said to be less than $g$ according to the **stable ordering** just in case

$$f \leqslant^\text{st} g \overset{\text{def}}{=} \forall x, y \in D. x \leq y \implies f(x) = f(y) \wedge g(x).$$

**Problem 3**  
(i) Show that with the extensional ordering on the set $D \Rightarrow E$ of stable functions from $D$ to $E$, the application function $(D \Rightarrow E) \times D \to E$ is not stable.

(ii) Prove that application is stable if and only if $D \Rightarrow E$ is ordered stably.

**Problem 4**  
(i) Show (informally) that stable functions give a model of Pcf.

(ii) Show that parallel-or is not definable in the model.
