NATURAL HOMOTOPY OF MULTIPONTED D-SPACES

PHILIPPE GAUCHER

Abstract. We identify Grandis’ directed spaces as a full reflective subcategory of the category of multipointed d-spaces. When the multipointed d-space realizes a precubical set, its reflection coincides with the standard realization of the precubical set as a directed space. The reflection enables us to extend the construction of the natural system of topological spaces in Baues-Wirsching’s sense from directed spaces to multipointed d-spaces. In the case of a cellular multipointed d-space, there is a discrete version of this natural system which is proved to be bisimilar up to homotopy. We also prove that these constructions are invariant up to homotopy under globular subdivision. These results are the globular analogue of Dubut’s results. Finally, we point the incompatibility between the notion of bisimilar natural systems and the q-model structure of multipointed d-spaces. This means that either the notion of bisimilar natural systems is too rigid or new model structures should be considered on multipointed d-spaces.

1. INTRODUCTION

Presentation. Directed spaces are topological spaces equipped with a set of continuous paths called directed paths closed under non-decreasing reparametrization and under composition and containing the constant paths [20, Definition 1.1]. They are one of the geometric models of concurrency studied in Directed Algebraic Topology (DAT) [9]. In his doctoral dissertation [4], Jérémie Dubut studies some natural systems in Baues-Wirsching’s sense associated with a directed space. The purpose of this approach is to obtain global invariants of directed spaces, meaning algebraic objects capable of reducing
the size of the state space without destroying the causal structure. Preserving this causal structure is the central problem of DAT, due to the nonconventional behavior of the directed segment. Indeed, the preservation of the causal structure requires extreme caution before contracting a segment in the direction of time. One of Dubut’s results is the proof that some natural system associated with the realization as a directed space of a cubical complex is bisimilar to a discrete version of this construction [4, Section 8.3.2 and 8.3.3] (see also [5, Theorem 1]). An immediate consequence is the invariance under cubical subdivision of these constructions, up to bisimilarity. This result proves the relevance of the notion of bisimilarity of natural systems for DAT. Another interesting feature of this approach is the homological properties of the category of all small diagrams of e.g. abelian groups, which seems to pave the way towards calculations using generalizations of homological algebra.

The aim of this paper is to present the globular analogue of Dubut’s results. The starting point is the following observation.

**Theorem.** *(Theorem 3.5 and Theorem 3.6)* The directed spaces in the sense of [20, Definition 1.1] are a full reflective subcategory of the category of multipointed d-spheres in the sense of [17, Definition 3.4].

The reflection $\overrightarrow{Sp}$ takes a multipointed d-space to a directed space such that the directed paths are all finite compositions of pieces of execution paths. The image by the functor $\overrightarrow{Sp}$ of the realization of a precubical set as a multipointed d-space is the standard realization of a precubical set as a directed space (see the end of Section 3). This enables us to define a natural system in Baues-Wirsching’s sense of topological spaces $\overrightarrow{NT}(X)$ associated with a multipointed d-space $X$ which extends the construction on directed spaces presented in [4, Section 6.4]. In the cellular case, we find a discrete version $\overrightarrow{NT}_d(X)$ of this natural system. We prove that the latter is bisimilar up to homotopy to the former one. Unlike what happens in the cubical setting, the globular version of these results does not require to restrict to objects equipped with a global order. Finally, we also prove that these constructions are invariant up to homotopy under the T-homotopy equivalences as introduced in [19, Definition 4.10] and which are preferably called *globular subdivisions* in this paper (see Figure 5). These results are summarized in the following statements:

**Theorem.** *(Theorem 8.16)* Let $X$ be a cellular multipointed d-space. There exists a map of natural systems of topological spaces from $\overrightarrow{NT}(X)$ to its discrete version $\overrightarrow{NT}_d(X)$ which is open up to homotopy. Consequently, these two natural systems are bisimilar up to homotopy.

**Theorem.** *(Theorem 9.4)* A globular subdivision is a map $f : X \to Y$ between cellular multipointed d-spaces inducing a homeomorphism between the underlying spaces (see Figure 5). In this situation, we prove that the natural systems of topological spaces $\overrightarrow{NT}(X)$, $\overrightarrow{NT}(Y)$, $\overrightarrow{NT}_d(X)$ and $\overrightarrow{NT}_d(Y)$ are bisimilar up to homotopy.

The very last result of this paper is a negative result. Proposition 10.1 establishes that there exist two cellular multipointed d-spaces which are weakly equivalent in the q-model structure of multipointed d-spaces and such that the associated natural systems are not bisimilar up to homotopy. The counterexample does not use far-fetched multipointed d-spaces. They are both obtained by starting from a very simple finite loop-free precubical
set of dimension 1. This negative result means that the two approaches of DAT which are on one hand the model structures on multipointed $d$-spaces of [16] and on the other hand the notion of bisimilar natural systems seem to be incompatible. This suggests that either new model categories must be introduced, or the notion of bisimilar natural systems is too rigid. We have no indication of how to bridge the gap between the two approaches at present.

Outline of the paper. Section 2 expounds some very basic notions and results about Moore paths and the regular ones. Some facts are generalizations or adaptations of statements coming from [14, 17]. It is important to notice that, in this paper, we do work with constant paths as well.

Section 3 constructs the functor $Sp$ from the category of multipointed $d$-spaces to the category of directed spaces. In this paper, a directed space means a $d$-space in Grandis’ sense [20, Definition 1.1]. We prefer this terminology, also sometimes used in the literature, to avoid any confusion with multipointed $d$-spaces.

Section 4 explores the basic properties of the directed paths of a cellular multipointed $d$-space. The important notion of discrete trace is introduced and it is proved that every directed path of a cellular multipointed $d$-space has a unique discrete trace.

Section 5 recalls some facts about the bisimilarity of diagrams and introduces the notion of bisimilarity up to homotopy and of open map up to homotopy.

Section 6 presents the construction of a functor from the category of multipointed $d$-spaces to the category of all small diagrams of topological spaces which takes a multipointed $d$-space $X$ to its natural system $\rightarrow NT(X)$.

Section 7 recalls an important fact about the passage from directed paths to traces which will be used in this paper. Proposition 7.1 is certainly not the most general valid statement. It is adapted to the use made in this paper.

Section 8 introduces the discrete version $\rightarrow NT_d(X)$ of $\rightarrow NT(X)$ for a cellular multipointed $d$-space $X$ and establishes Theorem 8.16.

Section 9 is devoted to the globular subdivisions and to the proof of Theorem 9.4.

Section 10 describes the incompatibility between the q-model structure of multipointed $d$-spaces and the notion of bisimilar natural systems. It is concluded by a final discussion by studying the cases of two directed spaces not containing globes.

Prerequisites and notations. We refer to [1] for locally presentable categories. The set of maps from $X$ to $Y$ of a (locally small) category $\mathcal{C}$ is denoted by $\mathcal{C}(X,Y)$.

Acknowledgments. I thank Jérémy Dubut for answering my questions about his doctoral dissertation.

2. Moore paths and regular paths

The category $\text{Top}$ denotes either the category of $\Delta$-generated spaces or of $\Delta$-Hausdorff $\Delta$-generated spaces (cf. [15, Section 2 and Appendix B]). It is Cartesian closed by a result due to Dugger and Vogt recalled in [11, Proposition 2.5] and locally presentable by [10, Corollary 3.7]. The internal hom is denoted by $\text{TOP}(\mathcal{C})$. The right adjoint of the inclusion from $\Delta$-generated spaces to general topological spaces is called the $\Delta$-kelleyfication.
The notations \( \ell, \ell', \ell_i, L \ldots \) mean a nonnegative real number. \([\ell, \ell']\) denotes a segment: unless specified, it is always understood that \( \ell \leq \ell' \). Let \( \mu_\ell : [0, \ell] \to [0, 1] \) be the homeomorphism defined by \( \mu_\ell(t) = t/\ell \) for \( \ell > 0 \).

Let \( \mathcal{M}(\ell, \ell') \) be the set of non decreasing surjective maps from \([0, \ell]\) to \([0, \ell']\) equipped with the \( \Delta \)-kelleyfication of the relative topology induced by the set inclusion \( \mathcal{M}(\ell_1, \ell_2) \subset \text{TOP}([0, \ell_1], [0, \ell_2]) \). Note that, by an argument similar to the one of [14, Proposition 2.5], we see that the topology of \( \mathcal{M}(\ell, \ell') \) coincides with the compact-open topology and with the pointwise convergence topology.

2.1. Notation. Let \( \phi_i \in \mathcal{M}(\ell_i, \ell'_i) \) for \( n \geq 1 \) and \( 1 \leq i \leq n \). Then the map

\[
\phi_1 \otimes \ldots \otimes \phi_n : \sum \ell_i \longrightarrow \sum \ell'_i
\]

denotes the non-decreasing surjective map defined by

\[
(\phi_1 \otimes \ldots \otimes \phi_n)(t) = \begin{cases} 
\phi_1(t) & \text{if } 0 \leq t \leq \ell_1 \\
\phi_2(t - \ell_1) + \ell'_1 & \text{if } \ell_1 \leq t \leq \ell_1 + \ell_2 \\
\vdots & \\
\phi_i(t - \sum_{j<i} \ell_j) + \sum_{j<i} \ell'_j & \text{if } \sum_{j<i} \ell_j \leq t \leq \sum_{j<i} \ell_j \\
\vdots & \\
\phi_n(t - \sum_{j<n} \ell_j) + \sum_{j<n} \ell'_j & \text{if } \sum_{j<n} \ell_j \leq t \leq \sum_{j<n} \ell_j.
\end{cases}
\]

2.2. Definition. Let \( U \) be a topological space. A \((Moore)\) path of \( U \) consists of a continuous map \( \gamma : [0, \ell] \to U \). The real number \( \ell \) is called the length of \( \gamma \). Remember that in this paper, and unlike some previous papers like [14, 17, 18], we also consider Moore paths of length 0.

2.3. Definition. Let \( \gamma_1 : [0, \ell_1] \to U \) and \( \gamma_2 : [0, \ell_2] \to U \) be two Moore paths of a topological space \( U \) such that \( \gamma_1(\ell_1) = \gamma_2(0) \). The Moore composition \( \gamma_1 \ast \gamma_2 : [0, \ell_1 + \ell_2] \to U \) is the Moore path defined by

\[
(\gamma_1 \ast \gamma_2)(t) = \begin{cases} 
\gamma_1(t) & \text{for } t \in [0, \ell_1] \\
\gamma_2(t - \ell_1) & \text{for } t \in [\ell_1, \ell_1 + \ell_2].
\end{cases}
\]

The Moore composition of Moore paths is strictly associative.

2.4. Definition. Let \( \gamma_1 \) and \( \gamma_2 \) be two continuous maps from \([0, 1]\) to some topological space such that \( \gamma_1(1) = \gamma_2(0) \). The composite defined by

\[
(\gamma_1 \ast_N \gamma_2)(t) = \begin{cases} 
\gamma_1(2t) & \text{if } 0 \leq t \leq \frac{1}{2}, \\
\gamma_2(2t - 1) & \text{if } \frac{1}{2} \leq t \leq 1
\end{cases}
\]

is called the normalized composition. One has \( \gamma_1 \ast_N \gamma_2 = (\gamma_1 \mu_{1/2}) \ast (\gamma_2 \mu_{1/2}) \).

2.5. Proposition. Let \( \ell_1, \ell'_1, \ldots, \ell_n, \ell'_n \geq 0 \). Let \( U \) be a topological space. Let \( \gamma_i : [0, \ell'_i] \to U \) be \( n \) continuous maps with \( 1 \leq i \leq n \) and \( n \geq 1 \). Let \( \phi_i : [0, \ell_i] \to [0, \ell'_i] \) be a non-decreasing surjective map for \( 1 \leq i \leq n \). Then we have

\[
(\gamma_1 \ast \ldots \ast \gamma_n)(\phi_1 \otimes \ldots \otimes \phi_n) = (\gamma_1 \phi_1) \ast \ldots \ast (\gamma_n \phi_n).
\]
Proof. For \( \sum_{j<i} \ell_j \leq t \leq \sum_{j\leq i} \ell_j \), we have
\[
(\gamma_1 \ast \cdots \ast \gamma_n)(\phi_1 \otimes \cdots \otimes \phi_n)(t) = \gamma_i((\phi_1 \otimes \cdots \otimes \phi_n)(t) - \sum_{j<i} \ell'_j)
= \gamma_i((\phi_i(t - \sum_{j<i} \ell_j) + \sum_{j<i} \ell'_j) - \sum_{j<i} \ell'_j)
= \gamma_i(\phi_i(t - \sum_{j<i} \ell_j))
= (\gamma_1 \phi_1) \ast \cdots \ast (\gamma_n \phi_n)(t),
\]
the first and the fourth equality by definition of the Moore composition, the second equality by definition of \( \phi_1 \otimes \cdots \otimes \phi_n \), and the third equality by algebraic simplification. \( \square \)

2.6. Proposition. [14, Proposition 3.5] Let \( U \) be a topological space. Let \( \gamma_i : [0,1] \to U \) be \( n \) continuous maps with \( 1 \leq i \leq n \) and \( n \geq 1 \). Let \( \ell_i > 0 \) with \( 1 \leq i \leq n \) nonzero real numbers with \( \sum_i \ell_i = 1 \). Then for all \( \ell > 0 \), we have
\[
\left((\gamma_1 \mu_{\ell_1}) \ast \cdots \ast (\gamma_n \mu_{\ell_n})\right)\mu_\ell = (\gamma_1 \mu_{\ell_1 \ell}) \ast \cdots \ast (\gamma_n \mu_{\ell_n \ell}).
\]

2.7. Definition. [7, Definition 1.1] Let \( U \) be a topological space. The Moore path \( \gamma : [0, L] \to U \) is regular if \( \gamma \) is constant or if for any in interval \( [a, b] \subset [0, L] \) with \( a \leq b \) such that the restriction \( \gamma \mid_{[a,b]} \) is constant, one has \( a = b \).

The Moore composition of two non-constant regular paths is regular. The main property of regular paths for this paper is the following one:

2.8. Proposition. Let \( U \) be a Hausdorff topological space. Let \( p, q : [0,1] \to U \) be two non-constant regular paths such that there exists \( \phi \in \mathcal{M}(1,1) \) such that \( p = q \phi \). Then \( \phi \) is a homeomorphism from \([0,1]\) to itself.

Proof. It is [7, Proposition 3.8]. \( \square \)

Proposition 2.8 is used only in Theorem 9.3 where \( U \) is the underlying space of a cellular multipointed \( d \)-space. The latter is always Hausdorff: see Section 4.

3. From multipointed \( d \)-spaces to directed spaces

3.1. Definition. [17, Definition 3.4] A multipointed \( d \)-space \( X \) is a triple \((|X|, X^0, \mathbb{P}^{\text{top}} X)\)
where
- The pair \((|X|, X^0)\) is a multipointed space. The space \(|X|\) is called the underlying space of \( X \) and the set \( X^0 \) the set of states of \( X \).
- The set \( \mathbb{P}^{\text{top}} X \) is a set of continuous maps from \([0,1]\) to \(|X|\) called the execution paths, satisfying the following axioms:
  - For any execution path \( \gamma \), one has \( \gamma(0), \gamma(1) \in X^0 \).
  - Let \( \gamma \) be an execution path of \( X \). Then any composite \( \gamma \phi \) with \( \phi \in \mathcal{M}(1,1) \) is an execution path of \( X \).
  - Let \( \gamma_1 \) and \( \gamma_2 \) be two composable execution paths of \( X \); then the normalized composition \( \gamma_1 \ast_N \gamma_2 \) is an execution path of \( X \).

A map \( f : X \to Y \) of multipointed \( d \)-spaces is a map of multipointed spaces from \((|X|, X^0)\) to \((|Y|, Y^0)\) such that for any execution path \( \gamma \) of \( X \), the map \( \mathbb{P}^{\text{top}} f : \gamma \mapsto f.\gamma \)
is an execution path of $Y$. The category of multipointed $d$-spaces is denoted by $\text{MdTop}$. Let $\mathbb{P}^{\text{top}}_{\alpha,\beta} X = \{ \gamma \in \mathbb{P}^{\text{top}} X \mid \gamma(0) = \alpha, \gamma(1) = \beta \}$. Let $\mathbb{P}^\ell_{\alpha,\beta} X = \{ \gamma_{\mu} \mid \gamma \in \mathbb{P}^{\text{top}}_{\alpha,\beta} X \}$. The elements of $\mathbb{P}^\ell_{\alpha,\beta} X$ are called the execution paths of length $\ell$.

The category $\text{MdTop}$ is locally presentable, and in particular bicomplete, by e.g [17, Proposition 3.6] which is an adaptation of [11, Theorem 3.5]. In particular, it is bicomplete.

3.2. Notation. Denote by $\mathcal{I}(\ell)$ the set of non-decreasing continuous maps from $[0,1]$ to $[0,\ell]$. Note that an element of $\mathcal{I}(\ell)$ can be a constant map.

3.3. Definition. [20, Definition 1.1] [9, Definition 4.1] A directed space is a pair $X = (|X|, d(X))$ such that

- $|X|$ is a topological space;
- $d(X)$ is a set of continuous paths from $[0,1]$ to $|X|$;
- $d(X)$ contains all constant paths;
- $d(X)$ is closed under normalized composition;
- $d(X)$ is closed under reparametrization by an element of $\mathcal{I}(1)$.

The space $|X|$ is called the underlying topological space. The elements of $d(X)$ are called directed paths. A morphism of directed spaces is a continuous map between the underlying topological spaces which takes a directed path of the source to a directed path of the target. The category of directed spaces is denoted by $\text{dTop}$. Write $\overrightarrow{\text{Sp}}(X)(u,v)$ for the space of directed paths of $X$ from $u$ to $v$ equipped with the $\Delta$-kelleyfication of the compact-open topology.

We use the terminology directed space instead of the one of $d$-space to avoid any confusion in this work with the multipointed $d$-spaces. Besides, directed spaces have directed paths and multipointed $d$-spaces have execution paths.

The category $\text{dTop}$ is locally presentable. In particular, it is bicomplete. The proof is not strictly speaking in [10] although the latter paper contains the material. It suffices to start with a small relational universal strict Horn theory $\mathcal{T}$ axiomatizing $\text{Top}$ (without equality by [10, Theorem 3.6] when $\text{Top}$ is the category of $\Delta$-generated spaces, and with equality by [15, Proposition B.18] when $\text{Top}$ is the category of $\Delta$-Hausdorff $\Delta$-generated spaces). The notion of directed space is axiomatized using the axioms expounded in the proof of [10, Theorem 4.2]. The proof is complete thanks to [1, Theorem 5.30].

3.4. Proposition. Let $X$ be a multipointed $d$-space. Consider the set of paths $d(X)$ which consists of all constant paths and all Moore compositions of the form

$$(\gamma_1, \phi_1, \mu_{\ell_1}) \ast \cdots \ast (\gamma_n, \phi_n, \mu_{\ell_n})$$

such that $\ell_1 + \cdots + \ell_n = 1$ where $\gamma_1, \ldots, \gamma_n$ are execution paths of $X$ and $\phi_i \in \mathcal{I}(1)$ for $i = 1, \ldots, n$. Then the pair $(|X|, d(X))$ is a directed space denoted by $\overrightarrow{\text{Sp}}(X)$. The mapping $X \mapsto \overrightarrow{\text{Sp}}(X)$ induces a functor $\overrightarrow{\text{Sp}} : \text{MdTop} \to \text{dTop}$ from multipointed $d$-spaces to directed spaces.

Proof. Let $d(X)$ be the set of continuous paths described in the statement of the theorem.
(1) By definition, the set $d(X)$ contains all constant paths.

(2) Let $\Gamma = (\gamma_1 \phi_1 \mu_{\ell_1}) \ast \cdots \ast (\gamma_n \phi_n \mu_{\ell_n})$ and $\Gamma' = (\gamma'_1 \phi'_1 \mu_{\ell'_1}) \ast \cdots \ast (\gamma'_n \phi'_n \mu_{\ell'_n})$ be two composable elements of $d(X)$. Then

$$
\Gamma \ast_N \Gamma' = (\Gamma \mu_{1/2}) \ast (\Gamma' \mu_{1/2})
$$

the first equality by definition of the normalized composition, and the second equality by Proposition 2.6 applied to the continuous maps $\gamma_i \phi_i$, $\gamma'_i \phi'_i : [0,1] \rightarrow |X|$. Thus the normalized composition of two paths of $d(X)$ is a path of $d(X)$.

(3) Let $\phi \in \mathcal{I}(1)$. Let $\Gamma \in d(X)$. When $\phi(0) = \phi(1)$ or when $\Gamma$ is constant, $\Gamma \phi$ is constant as well and therefore $\Gamma \phi \in d(X)$. Assume now that $\Gamma$ is a non-constant path and that $0 \leqslant \phi(0) < \phi(1) \leqslant 1$. Let $\Gamma = (\gamma_1 \phi_1 \mu_{\ell_1}) \ast \cdots \ast (\gamma_n \phi_n \mu_{\ell_n})$. Using Proposition 2.5 applied to the continuous maps $\gamma_i \phi_i : [0,1] \rightarrow |X|$, write

$$
\Gamma = \left( (\gamma_1 \phi_1) \ast \cdots \ast (\gamma_n \phi_n) \right) (\mu_{\ell_1} \otimes \cdots \otimes \mu_{\ell_n}).
$$

This implies

$$
\Gamma \phi = \left( (\gamma_1 \phi_1) \ast \cdots \ast (\gamma_n \phi_n) \right) (\mu_{\ell_1} \otimes \cdots \otimes \mu_{\ell_n}) \phi.
$$

One has $\psi \in \mathcal{I}(n)$. Since $\mu_{\ell_1} \otimes \cdots \otimes \mu_{\ell_n}$ is a non-decreasing homeomorphism from $[0,1]$ to $[0,n]$, $\phi(0) < \phi(1)$ implies $\psi(0) < \psi(1)$. Let $r, s$ be the two unique integers such that

$$
r = \max \{ p \in \mathbb{N} : p < \psi(0) \} \quad \psi(0) < \psi(1) \leqslant s = \min \{ p \in \mathbb{N} : \psi(1) \leqslant p \}.
$$

This implies that $r \leqslant \psi(0) < r + 1$ and $s - 1 < \psi(1) \leqslant s$. From the equality $\psi(0) < \psi(1)$, we deduce that $r < s$, or equivalently $s - r \geqslant 1$. Then for all $t \in [0,1]$, one has by definition of the Moore composition

$$
\Gamma \phi(t) = \left( (\gamma_{r+1} \phi_{r+1}) \ast \cdots \ast (\gamma_s \phi_s) \right) (\psi(t) - r).
$$

By definition of the Moore composition again, one obtains

$$
\Gamma \phi(t) = \begin{cases}
\gamma_{r+1} \phi_{r+1}(\psi(t) - r) & \text{if } \psi(0) < \psi(t) \leqslant r + 1 \\
\gamma_{r+2} \phi_{r+2}(\psi(t) - (r + 1)) & \text{if } r + 1 \leqslant \psi(t) \leqslant r + 2 \\
\cdots & \text{if } s - 1 \leqslant \psi(t) \leqslant \psi(1) \\
\gamma_s \phi_s(\psi(t) - (s - 1)) & \text{if } s - 1 \leqslant \psi(t) \leqslant \psi(1).
\end{cases}
$$

Let $L_0 = 0$, $L_i \in [0,1]$ such that $\psi(L_i) = r + i$ for $1 \leqslant i \leqslant s - r - 1$ and $L_{s-r} = 1$. The case $s - r = 1$ means there are only two terms $L_0 = 0$ and $L_1 = 1$. In this case, $L_0 < L_1$. In the case $s - r > 1$, one has

$$
\psi(L_0) = \psi(0) < r + 1 = \psi(L_1) \\
\psi(L_i) = r + i < r + i + 1 = \psi(L_{i+1}) \quad \text{for } 1 \leqslant i < i + 1 \leqslant s - r - 1 \\
\psi(L_{s-r-1}) = s - 1 < \psi(1) = \psi(L_{s-r}).
$$
In all cases, we deduce the strict inequalities
\[ \psi(L_0) < \psi(L_1) < \cdots < \psi(L_{s-r}). \]
This implies that \( 0 = L_0 < L_1 < \cdots < L_{s-r} = 1 \), \( \psi \) being non-decreasing. We obtain
\[
\Gamma \phi(t) = \begin{cases} 
\gamma_{r+1} \phi_{r+1}(\psi(t) - r) & \text{if } L_0 \leq t \leq L_1 \\
\gamma_{r+2} \phi_{r+2}(\psi(t) - (r+1)) & \text{if } L_1 \leq t \leq L_2 \\
\vdots & \\
\gamma_s \phi_s(\psi(t) - (s-1)) & \text{if } L_{s-r-1} \leq t \leq L_{s-r}.
\end{cases}
\]

Let
\[
\bar{\phi}_{r+1}(u) = \phi_{r+1}(\psi(u + L_0) - r) \text{ if } 0 \leq u \leq L_1 - L_0 \\
\bar{\phi}_{r+2}(u) = \phi_{r+2}(\psi(u + L_1) - (r+1)) \text{ if } 0 \leq u \leq L_2 - L_1 \\
\vdots \\
\bar{\phi}_s(u) = \phi_s(\psi(u + L_{s-r-1}) - (s-1)) \text{ if } 0 \leq u \leq L_{s-r} - L_{s-r-1}.
\]

Then, by definition of the Moore composition, we deduce
\[
\Gamma \phi = (\gamma_{r+1} \bar{\phi}_{r+1}) \ast \cdots \ast (\gamma_s \bar{\phi}_s) \\
= (\gamma_{r+1} \bar{\phi}_{r+1} \bar{\mu}_{L_1 - L_0} \bar{\mu}_{L_1 - L_0}^{-1}) \ast \cdots \ast (\gamma_s \bar{\phi}_s \bar{\mu}_{L_{s-r} - L_{s-r-1}} \bar{\mu}_{L_{s-r} - L_{s-r-1}}^{-1}).
\]
By hypothesis, the maps \( \bar{\phi}_{r+1}, \ldots, \bar{\phi}_s \) belong to \( \mathcal{I}(1) \). Since \( \psi \) is non-decreasing, belonging to \( \mathcal{I}(n) \) by definition, the maps \( \bar{\phi}_{r+1} \bar{\mu}_{L_1 - L_0}, \ldots, \bar{\phi}_s \bar{\mu}_{L_{s-r} - L_{s-r-1}} \) belong to \( \mathcal{I}(1) \) as well. We have proved that \( \Gamma \phi \in d(X) \).

(4). Let \( f : X \to Y \) be a map of multipointed \( d \)-spaces. Then \( f \) takes constant paths of \( X \) to constant paths of \( Y \) and an element of the form \( (\gamma_1 \bar{\phi}_1 \mu_{\ell_1}) \ast \cdots \ast (\gamma_n \bar{\phi}_n \mu_{\ell_n}) \) to \( (f \gamma_1 \bar{\phi}_1 \mu_{\ell_1}) \ast \cdots \ast (f \gamma_n \bar{\phi}_n \mu_{\ell_n}) \). Since \( f \gamma_1, \ldots, f \gamma_n \) are execution paths of \( Y \), the mapping \( X \mapsto \Sp(X) \) induces a functor from multipointed \( d \)-spaces to directed spaces.

\[ \square \]

3.5. Theorem. The functor
\[ \Sp : \mathrm{MtdTop} \to \mathrm{dTop} \]
is a left adjoint. The right adjoint is the functor denoted by
\[ \Omega : \mathrm{dTop} \to \mathrm{MtdTop} \]
from directed spaces to multipointed \( d \)-spaces which takes a directed space \((|Y|, d(Y))\) to the multipointed \( d \)-space \((|Y|, |Y|, d(Y))\).

Proof. Let \( X \) be a multipointed \( d \)-space. Let \( Y \) be a directed space. By Proposition 3.4, there is a unique set map \( \ell \) from \( \mathrm{dTop}(\Sp(X), Y) \) to \( \mathrm{MtdTop}(X, \Omega(Y)) \) such that the following diagram of sets
\[
\begin{array}{ccc}
\mathrm{dTop}(\Sp(X), Y) & \xrightarrow{\ell} & \mathrm{MtdTop}(X, \Omega(Y)) \\
\downarrow & & \downarrow \\
\mathrm{Top}(|X|, |Y|) & \xrightarrow{\text{bij}} & \mathrm{Top}(|X|, |Y|)
\end{array}
\]
is commutative where the vertical maps take a map to the corresponding map between the underlying spaces. Similarly, by Proposition 3.4, there is a unique set map $\ell'$ from $\mathcal{MdTop}(X, \overrightarrow{\Omega}(Y))$ to $\mathbf{dTop}(\mathbf{Sp}(X), Y)$ such that the following diagram of sets

$$
\mathcal{MdTop}(X, \overrightarrow{\Omega}(Y)) \xrightarrow{-\rightarrow \ell'} \mathbf{dTop}(\mathbf{Sp}(X), Y)
$$

$$
\Top(|X|, |Y|) \xrightarrow{\ell'} \Top(|X|, |Y|)
$$

is commutative. We deduce that $\ell\ell'$ is the unique map making the diagram

$$
\mathcal{MdTop}(X, \overrightarrow{\Omega}(Y)) \xrightarrow{\ell\ell'} \mathcal{MdTop}(X, \overrightarrow{\Omega}(Y))
$$

$$
\Top(|X|, |Y|) \xrightarrow{\ell\ell'} \Top(|X|, |Y|)
$$

commutative. Thus $\ell\ell'$ is the identity of $\mathcal{MdTop}(X, \overrightarrow{\Omega}(Y))$. Similarly, we obtain that $\ell'\ell$ is the identity of $\mathbf{dTop}(\mathbf{Sp}(X), Y)$. Hence the proof is complete.

Since the categories $\mathbf{dTop}$ and $\mathcal{MdTop}$ are locally presentable, it is possible to use a different argument to prove that the functor $\overrightarrow{\Omega} : \mathbf{dTop} \rightarrow \mathcal{MdTop}$ is a right adjoint. From the natural bijection of sets

$$
\Top([0,1], \lim_i Z_i) \cong \lim_i \Top([0,1], Z_i)
$$

for all small diagrams of topological spaces $i \mapsto Z_i$, we see easily that the functor $\overrightarrow{\Omega}$ is limit-preserving. Since the set of directed paths (of execution paths resp.) of a colimit of directed spaces (of multipointed $d$-spaces resp.) is the set of finite compositions of directed paths (of execution paths resp.) of the components, the functor $\overrightarrow{\Omega}$ is finitely accessible. Therefore by [1, Theorem 1.66], the functor $\overrightarrow{\Omega}$ is a right adjoint.

On the other hand, we do not see any argument to prove without calculations that the set of paths $d(X)$ of Proposition 3.4 satisfies the axioms of directed paths. From the abstract argument above, we can only conclude that the left adjoint $\mathbf{Sp}(X)$ contains as directed paths at least the set of paths $d(X)$ described in the statement of Proposition 3.4.

3.6. Theorem. For all directed spaces $X$, there is the equality $\mathbf{Sp}(\overrightarrow{\Omega}(X)) = X$. The category of directed spaces is isomorphic to a full reflective subcategory of the category of multipointed $d$-spaces $X$.

Proof. The counit $\mathbf{Sp}(\overrightarrow{\Omega}(X)) \rightarrow X$ of the adjunction $\mathbf{Sp} \dashv \overrightarrow{\Omega}$ induces the identity on the underlying space $|X|$. This implies that the identity of $|X|$ yields a one-to-one set map from the directed paths of $\mathbf{Sp}(\overrightarrow{\Omega}(X))$ to the directed path of $X$. Every directed path of $X$ is an execution path of the multipointed $d$-space $\overrightarrow{\Omega}(X)$ by definition of the functor $\overrightarrow{\Omega}$. By Proposition 3.4, we deduce that every directed path of $X$ is a directed path of $\mathbf{Sp}(\overrightarrow{\Omega}(X))$. We obtain the equality $\mathbf{Sp}(\overrightarrow{\Omega}(X)) = X$. Finally, for every multipointed $d$-space of the form $\overrightarrow{\Omega}(X)$, one has $\overrightarrow{\Omega}(\mathbf{Sp}(\overrightarrow{\Omega}(X))) = \overrightarrow{\Omega}(X)$ by the previous equality. Hence the isomorphism of categories.
To justify the relevance of the functor $\Phi^\to : \text{MdTop} \to \text{dTop}$ for DAT, we verify now that the directed spaces associated to the tame and non-tame realizations of a precubical set as a multipointed $d$-space are the same and that they coincide with the usual definition of the realization of a precubical set as a directed space. Proposition 3.10 being not used in the sequel, it is possible to skip the reading of this part of the section.

We recall a few definitions: see e.g. [9, 18, 25]. Let $[n] = \{0, 1\}^n$ for $n \geq 1$. Let $\{0, 1\}^0 = [0, 1]^0 = [0] = \{\cdot\}$. Let $\delta_i^n : [0, 1]^{n-1} \to [0, 1]^n$ be the continuous map defined for $1 \leq i \leq n$ and $\alpha \in \{0, 1\}$ by $\delta_i^n(\epsilon_1, \ldots, \epsilon_{n-1}) = (\epsilon_1, \ldots, \epsilon_{i-1}, \alpha, \epsilon_{i+1}, \ldots, \epsilon_{n-1})$. The small category $\square$ is the subcategory of the category of sets with the set of objects $\{[n], n \geq 0\}$ and generated by the coface maps $\delta_i^n$. A precubical set $K$ is a presheaf over $\square$. An element $c$ of $K_n$ is called a $n$-cube and we set $n = \dim(c)$. Let $\square[n] = \square(\cdot, [n])$ for $n \geq 0$. The mapping $[n] \mapsto [0, 1]^n$ yields a well-defined cocubical object of $\text{Top}$, i.e. a functor from $\square$ to $\text{Top}$. The geometric realization of the precubical set $K$ is the topological space

$$|K|_{\text{geom}} = \int_{\square[n] \in \square} K_n, [n, 0, 1]^n.$$ A directed path of $[0, 1]^n$ is a continuous map $\gamma : [0, 1] \to [0, 1]^n$ which is non-decreasing with respect to each axis of coordinates. It is tame if $\gamma(0), \gamma(1) \in \{0, 1\}^n$. A directed path of an $n$-cube $c$ of length $\ell \geq 0$ is a composite continuous map of the form $|c|_{\text{geom}} \gamma : [0, \ell] \to [0, 1]^n \to |K|_{\text{geom}}$ such that $\gamma : [0, \ell] \to [0, 1]^n$ is a directed path of length $\ell \geq 0$. A directed path in $|K|_{\text{geom}}$ of length $\ell \geq 0$ is a continuous path $[0, \ell] \to |K|_{\text{geom}}$ which is a Moore composition of the form $(|c_1|_{\text{geom}} \gamma_1) \ast \cdots \ast (|c_p|_{\text{geom}} \gamma_p)$ with $p \geq 1$. The choice of $c_1, \ldots, c_p$ is not unique. This definition of a directed path in $|K|_{\text{geom}}$ makes sense anyway since the coface maps preserve the local ordering. The directed path $\gamma$ is tame if each $\gamma_i$ for $1 \leq i \leq p$ is tame ([25, Section 2.9]).

3.7. Proposition. Let $n \geq 1$. The following data assemble into a multipointed $d$-space denoted by $[\square[n]]^t$:

- The underlying space is the topological $n$-cube $[0, 1]^n$.
- The set of states is $\{0, 1\}^n \subset [0, 1]^n$.
- The set of execution paths from $a$ to $b$ with $a < b \in \{0 < 1\}^n$ is the set of directed paths $[0, 1] \to [0, 1]^n$ from $a$ to $b$.
- The set of execution paths from $a$ to $b$ with $a > b$ is empty.

Let $[\square[0]]^t = \{\cdot\}$. The mapping $[n] \mapsto [\square[n]]^t$ yields a well-defined cocubical objects of $\text{MdTop}$.
This map induces an isomorphism of directed spaces of multipointed $d$-spaces with a directed path from $(0,...,0)$ to $(1,...,1)$ in $|K|_{\text{geom}}$.

Note that the underlying space of $|K|^t$ is the topological space $|K|_{\text{geom}}$.

This yields a colimit-preserving functor from precubical sets to multipointed $d$-spaces by \cite[Proposition 2.15]{18}. The chosen name $\text{tame realization}$ is because all execution paths of $|K|^t$ are tame. Another realization functor from precubical sets to multipointed $d$-spaces can be defined as follows (it is an adaptation to the non-regular case of \cite[Definition 7.1]{18}):

Let $K$ be a precubical set. The realization $|K|$ of $K$ is the multipointed $d$-space having as underlying space $|K|_{\text{geom}}$, the set of states $K_0$, and such that the set of execution paths from $\alpha$ to $\beta$ consists of the non-constant directed paths from $\alpha$ to $\beta$ in $|K|_{\text{geom}}$.

We obtain the important fact:

Let $K$ be a precubical set. The identity of $|K|_{\text{geom}}$ induces a map of multipointed $d$-spaces $|K|^t \rightarrow |K|$ from the tame realization to the realization of $K$. This map induces an isomorphism of directed spaces $\overrightarrow{\text{Sp}}(|K|^t) \cong \overrightarrow{\text{Sp}}(|K|)$.

Proof. The existence of the map of multipointed $d$-spaces $|K|^t \rightarrow |K|$ is due to the fact that the identity of $|K|_{\text{geom}}$ induces a one-to-one set map from the set of non-constant tame directed paths to the set of non-constant directed paths between two vertices in the geometric realization of $K$. Thus, by Proposition 3.4, and since the underlying map is one-to-one, there is a one-to-one set map from $d(|K|^t)$ to $d(|K|)$. To prove the isomorphism $\overrightarrow{\text{Sp}}(|K|^t) \cong \overrightarrow{\text{Sp}}(|K|)$, it remains to prove that every directed path of $\overrightarrow{\text{Sp}}(|K|)$ is a directed path of $\overrightarrow{\text{Sp}}(|K|^t)$. By Proposition 3.4, it suffices to prove that every execution path of $|K|$ is a directed path of $\overrightarrow{\text{Sp}}(|K|^t)$. Every execution path $\gamma$ of $|K|$ is a Moore composition of the form $\gamma = (|c_1|_{\text{geom}} \gamma_1) \cdots (|c_p|_{\text{geom}} \gamma_p)$ such that each directed path $\gamma_i$ in $[0,1]^{\dim(c_i)}$ is of length $\ell_i > 0$ with $\ell_1 + \cdots + \ell_p = 1$. Each directed path $\gamma_i$ can be precomposed with a directed path from $(0,...,0)$ to $\gamma_i(0)$ in $[0,1]^{\dim(c_i)}$ and postcomposed with a directed path from $\gamma_i(\ell_i)$ to $(1,...,1)$ in $[0,1]^{\dim(c_i)}$ to obtain a directed path $\overrightarrow{\gamma_i}$ of length $L_i \geq \ell_i > 0$ from $(0,...,0)$ to $(1,...,1)$ in $[0,1]^{\dim(c_i)}$. There exists a non-decreasing map $\phi_i : [0,\ell_i] \rightarrow [0,L_i]$ such that $\gamma_i = \overrightarrow{\gamma_i} \phi_i$ for each $i \in \{1,...,p\}$. We obtain

$$\gamma = \left(|c_1|_{\text{geom}} \overrightarrow{\gamma_1} \mu_{L_1} \phi_1 \overrightarrow{\ell_1} \mu_{\ell_1}\right) \cdots \left(|c_p|_{\text{geom}} \overrightarrow{\gamma_p} \mu_{L_p} \phi_p \overrightarrow{\ell_p} \mu_{\ell_p}\right).$$

Each $\overrightarrow{\gamma_i} \mu_{\ell_i}^{-1}$ being tame by definition, each $|c_i|_{\text{geom}} \overrightarrow{\gamma_i} \mu_{\ell_i}^{-1}$ is an execution path of $|K|^t$. Each $\mu_{L_i} \phi_i \overrightarrow{\ell_i} \mu_{\ell_i}$ for $1 \leq i \leq p$ belongs to $\mathcal{T}(1)$. Using Proposition 3.4, we deduce that $\gamma$ is a directed path of $\overrightarrow{\text{Sp}}(|K|^t)$. \hfill \Box
As a consequence of Proposition 3.4 and Proposition 3.10, the directed space $\overrightarrow{\text{Sp}}(|K|^1) \cong \overrightarrow{\text{Sp}}(|K|)$ is nothing else but the usual directed space associated with a precubical set as defined e.g. in [9].

4. The directed paths of a cellular multipointed $d$-space

The topological globe of $Z$, which is denoted by $\text{Glob}^{\text{top}}(Z)$, is the multipointed $d$-space defined as follows

- the underlying topological space is the quotient space $(0, 1) \sqcup (Z \times [0, 1])$
  $$(z, 0) = (z', 0) = 0, (z, 1) = (z', 1) = 1$$
- the set of states is $\{0, 1\}$
- the set of execution paths is the set of continuous maps
  $$\{\delta_z \phi \mid \phi \in \mathcal{M}(1, 1), z \in Z\}$$
  with $\delta_z(t) = (z, t)$. It is equal to the underlying set of the space $Z \times \mathcal{M}(1, 1)$.

In particular, $\text{Glob}^{\text{top}}(\emptyset)$ is the multipointed $d$-space $\{0, 1\} = (\{0, 1\}, \{0, 1\}, \emptyset)$. The directed segment is the multipointed $d$-space $\overrightarrow{T}^{\text{top}} = \text{Glob}^{\text{top}}(\{0\})$.

Let $n \geq 1$. Denote by $D^n = \{(x_1, \ldots, x_n) \in \mathbb{R}^n, x_1^2 + \cdots + x_n^2 \leq 1\}$ the $n$-dimensional disk, and by $S^{n-1} = \{(x_1, \ldots, x_n) \in \mathbb{R}^n, x_1^2 + \cdots + x_n^2 = 1\}$ the $(n-1)$-dimensional sphere. By convention, let $D^0 = \{0\}$ and $S^{-1} = \emptyset$.

A cellular multipointed $d$-space consists of a colimit-preserving functor

$$X : \lambda \rightarrow \mathcal{M}\text{dTop}$$

such that

- The multipointed $d$-space $X_0$ is a set, in other terms $X_0 = (X^0, X^0, \emptyset)$ for some set $X^0$.
- For all $\nu < \lambda$, there is a pushout diagram of multipointed $d$-spaces

$$\begin{array}{ccc}
\text{Glob}^{\text{top}}(S^{n-1}) & \overset{\gamma_\nu}{\longrightarrow} & X_\nu \\
\downarrow & & \downarrow \\
\text{Glob}^{\text{top}}(D^n) & \overset{\gamma_\nu}{\longrightarrow} & X_{\nu+1}
\end{array}$$

with $n_\nu \geq 0$.

4.1. Notation. Let $X_\lambda = \lim_{\nu < \lambda} X_\nu$ be the transfinite composition.

The cellular multipointed $d$-spaces are the cellular objects of the combinatorial model category whose definition is recalled in Section 10. Consider the non-cellular multipointed $d$-space $X$ depicted in Figure 2. It is defined as follows. The underlying space $|X|$ is the topological space $|X| = \{(u, u) \mid u \in [0, 1]\} \cup \{(u, 1 - u) \mid u \in [0, 1]\}$. Let $X^0 = \{(0, 0), (0, 1), (1, 0), (1, 1)\}$. Let $\mathbb{P}^{\text{top}}_{(0, 0), (1, 1)} X = \{t \mapsto (\phi(t), \phi(t)) \mid \phi \in \mathcal{M}(1, 1)\}$, $\mathbb{P}^{\text{top}}_{(0, 1), (1, 0)} X = \{t \mapsto (\phi(t), 1 - \phi(t)) \mid \phi \in \mathcal{M}(1, 1)\}$ and $\mathbb{P}^{\text{top}}_{a, b} X = \emptyset$ otherwise. Then the composite of the two thick directed paths of Figure 2 is not of the form $\gamma \phi$ where $\gamma$ is
an execution path of $X$ and where $\phi \in \mathcal{I}(1)$. We prove in Theorem 4.9 that all directed paths of a cellular multipointed $d$-space are of this form.

4.2. **Notation.** In the whole section, $X_\lambda$ stands for a cellular multipointed $d$-space like above.

The underlying topological space $|X_\lambda|$ is Hausdorff by [17, Proposition 4.4]. For all $\nu \leq \lambda$, there is the equality $X_0^\nu = X^0$. Denote by

$$c_\nu = |\text{Glob}^{\text{top}}(D^{n_\nu})| \setminus |\text{Glob}^{\text{top}}(S^{n_\nu - 1})|$$

the $\nu$-th cell of $X_\lambda$. It is called a *globular cell*. Like in the usual setting of CW-complexes, $\bar{g}_\nu$ induces a homeomorphism from $c_\nu$ to $\bar{g}_\nu(c_\nu)$ equipped with the relative topology. The map $\bar{g}_\nu : \text{Glob}^{\text{top}}(D^{n_\nu}) \to X_\lambda$ is called the *attaching map* of the globular cell $c_\nu$. The state $\bar{g}_\nu(0) \in X^0$ ($\bar{g}_\nu(1) \in X^0$ resp.) is called the *initial (final resp.) state* of $c_\nu$ and is denoted by $c^-_\nu$ ($c^+_\nu$ resp.). The integer $n_\nu + 1$ is called the *dimension* of the globular cell $c_\nu$. It is denoted by $\text{dim} c_\nu$. The states of $X^0$ are also called the *globular cells of dimension 0*. By convention, a state of $X^0$ viewed as a globular cell of dimension 0 is equal to its initial state and to its final state. Thus, for $\alpha \in X^0$, one has $\alpha = \alpha^+ = \alpha^-$. The set of globular cells of $X_\lambda$ is denoted by $\mathcal{C}(X_\lambda)$. The set of globular cells of dimension $n \geq 0$ of $X_\lambda$ is denoted by $\mathcal{C}_n(X_\lambda)$. In particular, $\mathcal{C}_0(X_\lambda) = X^0$.

4.3. **Notation.** Let $c \neq d$ be two globular cells of $X_\lambda$. The notation $c \preceq d$ means that either $c = d^-$ (which implies $\text{dim}(d) \geq 1$) or $c^+ = d$ (which implies $\text{dim}(c) \geq 1$).

4.4. **Definition.** A *discrete trace* is a finite sequence of globular cells $[c_1, \ldots, c_n]$ of $\mathcal{C}(X_\lambda)$ such that $c_1 \preceq \cdots \preceq c_n$.

4.5. **Proposition.** Let $x \in |X_\lambda|$. There exists a unique globular cell $\text{dt}(x)$ of $X_\lambda$ such that $x \in \text{dt}(x)$.

**Proof.** The underlying topological space $|X_\lambda|$ satisfies as a set the equality of sets

$$|X| = \coprod_{c \in \mathcal{C}(X_\lambda)} c.$$

4.6. **Theorem.** Let $\gamma$ be an execution path of $X_\lambda$. There is a unique decomposition of $\gamma$ of the form $\text{nat}^{\text{gl}}(\gamma) \phi$ with $\text{nat}^{\text{gl}}(\gamma) = (\bar{g}_{\nu_1} \delta_{z_1}) \ast \cdots \ast (\bar{g}_{\nu_n} \delta_{z_n})$, $n \geq 1$, $\nu_i < \lambda$ and $z_i \in D^{n_\nu_i} \setminus S^{n_\nu_i - 1}$ for $1 \leq i \leq n$, and $\phi \in \mathcal{M}(1, n)$.
Proof. It is a rephrasing of [17, Theorem 4.13].

4.7. Definition. The execution path \( \text{nat}^\text{gl}(\gamma) \) of Theorem 4.6 is called the globular naturalization of \( \gamma \). The sequence \( \text{Carrier}(\gamma) = [c_{i_1}, \ldots, c_{i_n}] \) of Theorem 4.6 is called in [14, 17] the carrier of \( \gamma \).

It is important to recall the following fact:

4.8. Proposition. The globular naturalization of any execution path of \( X_\lambda \) is regular.

Proof. Let \( \gamma \) be an execution path of \( X_\lambda \). Let \( \text{nat}^\text{gl}(\gamma) = (\overline{g_{\nu_1} \delta_{z_1}}) \cdots (\overline{g_{\nu_n} \delta_{z_n}}) \) with \( n \geq 1, \nu_i < \lambda \) and \( z_i \in D^{|\nu_i|} \setminus S^{n_{\nu_i} - 1} \). Each \( \overline{g_{\nu}} \) induces a homeomorphism from \( c_{\nu_i} \) to its image in \( |X_\lambda| \). Thus \( \text{nat}^\text{gl}(\gamma) \) is regular, the Moore composition of non-constant regular paths being regular.

4.9. Theorem. A continuous map from \([0, 1]\) to \( |X_\lambda| \) is a directed path of \( X_\lambda \), i.e. of \( \widetilde{\text{Sp}}(X_\lambda) \), if and only if it is of the form \( \gamma\phi \) where \( \gamma \) is an execution path of \( X_\lambda \) or a constant path and where \( \phi \in \mathcal{I}(1) \).

Proof. It suffices to prove that for any execution path \( \gamma \) and \( \gamma' \) of \( X_\lambda \) and any \( \phi, \phi' \in \mathcal{I}(1) \) such that \( \gamma\phi \) and \( \gamma'\phi' \) are two composable paths of \( |X_\lambda| \), i.e. \( \gamma\phi(1) = \gamma'\phi'(0) \), the normalized composition \( (\gamma\phi) \ast_N (\gamma'\phi') \) is of the form \( \gamma'' \phi'' \) where \( \gamma'' \) is an execution path of \( X_\lambda \) and \( \phi'' \in \mathcal{I}(1) \). Using Theorem 4.6, write

\[
\begin{align*}
\text{Carrier}(\gamma) &= [c_{i_1}, \ldots, c_{i_n}], \\
\text{Carrier}(\gamma') &= [c'_{i_1}, \ldots, c'_{i_{n'}}], \\
\text{nat}^\text{gl}(\gamma) &= (\overline{g_{\nu_1} \delta_{z_1}}) \cdots (\overline{g_{\nu_n} \delta_{z_n}}), \\
\text{nat}^\text{gl}(\gamma') &= (\overline{g'_{\nu_1} \delta'_{z'_1}}) \cdots (\overline{g'_{\nu_{n'}} \delta'_{z'_{n'}}}), \\
\gamma &= \text{nat}^\text{gl}(\gamma) \psi \quad \text{with} \quad \psi \in \mathcal{M}(1, n), \\
\gamma' &= \text{nat}^\text{gl}(\gamma') \psi' \quad \text{with} \quad \psi' \in \mathcal{M}(1, n').
\end{align*}
\]

There are two mutually exclusive cases: (1) \( \gamma\phi(1) = \gamma'\phi'(0) \in X^0 \), (2) \( \gamma\phi(1) = \gamma'\phi'(0) \notin X^0 \).

(1) From \( \gamma\phi(1) = \text{nat}^\text{gl}(\gamma) \psi \phi(1) \in X^0 \), we deduce that \( \psi\phi(1) \in \{0, 1, \ldots, n\} \), the execution path \( \text{nat}^\text{gl}(\gamma) \) being regular by Proposition 4.8. Similarly, from \( \gamma'\phi'(0) = \text{nat}^\text{gl}(\gamma') \psi' \phi'(0) \in X^0 \), we deduce that \( \psi'\phi'(0) \in \{0, 1, \ldots, n'\} \). We can suppose without lack of generality that \( \psi\phi(1) = n \) and \( \psi'\phi'(0) = 0 \). Then one obtains the sequence of equalities

\[
(\gamma\phi) \ast_N (\gamma'\phi') = (\gamma\phi \mu_{1/2}) \ast (\gamma'\phi' \mu_{1/2})
\]

\[
= (\text{nat}^\text{gl}(\gamma) \psi \phi_{1/2}) \ast (\text{nat}^\text{gl}(\gamma') \psi' \phi'_{1/2})
\]

\[
= (\text{nat}^\text{gl}(\gamma) \mid_{[\psi\phi(0), \psi\phi(1)]} \psi \phi_{1/2}) \ast (\text{nat}^\text{gl}(\gamma') \mid_{[\psi'\phi'(0), \psi'\phi'(1)]} \psi' \phi'_{1/2})
\]

\[
= (\text{nat}^\text{gl}(\gamma) \mid_{[\psi\phi(0), \psi\phi(1)]} \ast \text{nat}^\text{gl}(\gamma') \mid_{[\psi'\phi'(0), \psi'\phi'(1)]}) ((\psi \phi_{1/2}) \otimes (\psi' \phi'_{1/2}))
\]

the first one by definition of \( \ast_N \), the second third and fifth ones by trivial substitution, and the fourth one by Proposition 2.5. This implies that \( (\gamma\phi) \ast_N (\gamma'\phi') = \gamma'' \phi'' \) where \( \gamma'' \)
is an execution path of $X_\lambda$ with $
abla'' = \left(\text{nat}^g(\gamma) \ast \text{nat}^g(\gamma')\right)\mu^{-1}_{m+n}$ and
\[\phi'' = \mu_{m+n}(\psi\phi_{1/2}) \otimes (\psi'\phi'_{1/2}) \in \mathcal{I}(1)\).

(2). In this case, $\psi(1) \in [0, m]\{0, 1, \ldots, m\}$ and $\psi' \phi(0) \in [0, n]\{0, 1, \ldots, n\}$, the execution paths $\text{nat}^g(\gamma)$ and $\text{nat}^g(\gamma')$ being regular by Proposition 4.8. We can suppose without lack of generality that $n-1 < \psi(1) < n$ and $0 < \psi' \phi'(0) < 1$. From the equality $\gamma \phi(1) = \gamma' \phi'(0) \notin X^0$, we deduce that $\gamma \phi(1) = \gamma' \phi'(0) \in c_{\mu m} \cap c_{\nu'}$. From the set bijection
\[|X_\lambda| = X^0 \sqcup \prod_{\nu < \lambda} c_{\nu},\]
we obtain that $c_{\nu'} = c_{\nu_{\lambda}}$ (and $\nu_{\lambda} = \nu_{\lambda}'$). From the equality $\gamma \phi(1) = \gamma' \phi'(0)$, we also deduce the following equalities:
\[z_n = z',\]
\[\tilde{g}_{\nu'} \delta_{z_n} = \tilde{g}_{\nu'}' \delta_{z_1},\]
\[\tilde{g}_{\nu'}(z_n, \psi(1) - (n-1)) = \tilde{g}_{\nu'}'(z', \psi'(0)).\]

Let
\[
\Gamma = (\tilde{g}_{\nu'} \delta_{z_1}) \ast \cdots \ast (\tilde{g}_{\nu'} \delta_{z_n}) \ast (\tilde{g}_{\nu'}' \delta_{z_1}) \ast \cdots \ast (\tilde{g}_{\nu'}' \delta_{z_{\lambda'}})
\]
\[= (\tilde{g}_{\nu'} \delta_{z_1}) \ast \cdots \ast (\tilde{g}_{\nu_{\lambda - 1}} \delta_{z_{\lambda - 1}}) \ast (\tilde{g}_{\nu'}' \delta_{z_1}) \ast \cdots \ast (\tilde{g}_{\nu'}' \delta_{z_{\lambda'}}).\]

By definition of the normalized composition, there is the equality of continuous paths
\[\gamma \phi \ast_N (\gamma' \phi') = (\text{nat}^g(\gamma) \psi \phi_{1/2}) \ast (\text{nat}^g(\gamma') \psi' \phi'_{1/2}).\]

One obtains
\[\left((\gamma \phi) \ast_N (\gamma' \phi')\right)(t) = \begin{cases} 
\tilde{g}_{\nu'}(z_p, \psi(2t) - p) & \text{if } t \leq \frac{1}{2} \text{ and } p \leq \psi(2t) \leq p + 1 \\
\tilde{g}_{\nu'}(z_p, \psi'(2t - 1) - p) & \text{if } t \geq \frac{1}{2} \text{ and } p \leq \psi'(2t - 1) \leq p + 1.
\end{cases}\]

On the other hand, one has
\[\Gamma((\psi \phi_{1/2}) \otimes (\psi' \phi'_{1/2}))(t) = \tilde{g}_{\nu'}(z_p, \psi(2t) - p)\]
if $t \leq 1/2$ and $p \leq \psi(2t) \leq p + 1$ since $\Gamma = (\tilde{g}_{\nu'} \delta_{z_1}) \ast \cdots \ast (\tilde{g}_{\nu_{\lambda - 1}} \delta_{z_{\lambda - 1}}) \ast (\tilde{g}_{\nu'}' \delta_{z_1}) \ast \cdots \ast (\tilde{g}_{\nu'}' \delta_{z_{\lambda'}})$ and one has
\[\Gamma((\psi \phi_{1/2}) \otimes (\psi' \phi'_{1/2}))(t) = \tilde{g}_{\nu'}(z_p, \psi'(2t - 1) - p)\]
if $t \geq 1/2$ and $p \leq \psi'(2t - 1) \leq p + 1$ since $\Gamma = (\tilde{g}_{\nu'} \delta_{z_1}) \ast \cdots \ast (\tilde{g}_{\nu_{\lambda - 1}} \delta_{z_{\lambda - 1}}) \ast (\tilde{g}_{\nu'}' \delta_{z_1}) \ast \cdots \ast (\tilde{g}_{\nu'}' \delta_{z_{\lambda'}})$. We deduce that
\[\gamma \phi \ast_N (\gamma' \phi') = \Gamma((\psi \phi_{1/2}) \otimes (\psi' \phi'_{1/2})).\]
This implies that $(\gamma \phi) \ast_N (\gamma' \phi') = \gamma'' \phi''$ where $\gamma''$ is an execution path of $X_\lambda$ and $\phi'' \in \mathcal{I}(1)$ with
\[\gamma'' = \Gamma\mu^{-1}_{n+n_{\lambda}}\]
and
\[ \phi'' = \mu_{n+n'-1} \left( (\psi'\phi'_{1/2}) \otimes (\psi'\phi_{1/2}) \right) \in \mathcal{I}(1). \]

As a first application of Theorem 4.9, we can define the discrete trace of a directed path of a cellular multipointed d-spaces as follows. The formulation of Proposition 4.10 is close to [8, Definition 2.20]. Another application of Theorem 4.9 is given in Theorem 9.3.

4.10. Theorem. Let \( \gamma \) be a directed path of \( X_\lambda \). There exists a unique discrete trace \( dt(\gamma) = [c_1, \ldots, c_n] \) and a sequence of real numbers \( 0 = t_0 \leq t_1 \leq \ldots \leq t_n = 1 \) such that

- \( c_i \neq c_{i+1} \),
- \( t \in [t_{i-1}, t_i] \Rightarrow \gamma(t) \in \tilde{c}_i \),
- \( t \in [t_{i-1}, t_i) \Rightarrow dt(\gamma(t)) = c_i \),
- \( dt(\gamma(t_i)) \in \{c_i, c_{i+1}\} \),
- \( dt(\gamma(0)) = c_1 \) and \( dt(\gamma(1)) = c_n \).

Proof. Suppose at first that the directed path \( \gamma \) is an execution path of \( X_\lambda \). Using Theorem 4.6, let \( \text{Carrier}(\gamma) = [c_1, \ldots, c_n] \), \( \text{nat}^\#(\gamma) = (\tilde{g}_{c_1}\delta_{z_1}) \ast \cdots \ast (\tilde{g}_{c_n}\delta_{z_n}) \) and \( \gamma = \text{nat}^\#(\gamma)\psi \) with \( \psi \in \mathcal{M}(1, n) \). Then one has
\[ dt(\gamma) = [\tilde{g}_{c_1}(\bullet, 0), c_1, \tilde{g}_{c_1}(\bullet, 0), c_2, \ldots, \tilde{g}_{c_n}(\bullet, 0), c_n, \tilde{g}_{c_n}(\bullet, 1)], \]
the symbol \( \bullet \) meaning here that its value does not matter. Note that \( \text{Carrier}(\gamma) \neq dt(\gamma) \), the discrete trace of \( \gamma \) containing also 0-dimensional globular cells. In the general case, a directed path of \( X_\lambda \) is either of the form \( \gamma \phi \) with \( \phi \in \mathcal{I}(1) \) or a constant path by Theorem 4.9. In the first case, \( dt(\gamma \phi) \) will be a subsequence of \( dt(\gamma) \). In the case of a constant path \( x \), the discrete trace is given by \( [dt(x)] \) of Proposition 4.5.

4.11. Definition. Let \( \gamma \) be a directed path of \( X_\lambda \). The finite sequence of globular cells \( dt(\gamma) = [c_1, \ldots, c_n] \) of Theorem 4.10 is called the discrete trace of \( \gamma \). Note the abuse of notation, \( dt(x) \) meaning either the unique globular cell containing \( x \in |X_\lambda| \) and the discrete trace of the constant path \( x \).

5. Bisimilarity of diagrams up to homotopy

Let \( \mathcal{K} \) be a category. We gather some basic results about the category \( \text{Diag}(\mathcal{K}) \) of all small diagrams over all small categories defined as follows. An object of \( \text{Diag}(\mathcal{K}) \) is a functor \( F : I \to \mathcal{K} \) from a small category \( I \) to \( \mathcal{K} \). A morphism from \( F : I_1 \to \mathcal{K} \) to \( G : I_2 \to \mathcal{K} \) is a pair \( (f : I_1 \to I_2, \mu : F \Rightarrow G)_f \) where \( f \) is a functor and \( \mu \) is a natural transformation. If \( (g, \nu) \) is a map from \( G : I_2 \to \mathcal{K} \) to \( H : \mathcal{K} \to \mathcal{K} \), then the composite \( (g, \nu).f \) is defined by \( (g.f, (\nu.f) \circ \mu) \) where \( \circ \) means the composition of natural transformations. The identity of \( F : I_1 \to \mathcal{K} \) is the pair \( (\text{Id}_{I_1}, \text{Id}_F) \). It is well-known that when \( \mathcal{K} \) is locally presentable, the category \( \text{Diag}(\mathcal{K}) \) is locally presentable as well. I learnt the result from [3] and from a remark after the question [12]. For the convenience of the reader, the argument is recalled. First, we observe that the forgetful functor from \( \text{Diag}(\mathcal{K}) \) to the category of small categories \( \mathbf{Cat} \) is a bifibred category by e.g. [15, Proposition A.1]. It corresponds to an accessible pseudo-functor in the sense of [23, Definition 5.3.1] and we use [23, Theorem 5.3.4] to complete the proof.
5.1. Definition. [6, Section 2.3] Two objects $F : \mathcal{I} \to \mathcal{K}$ and $G : \mathcal{J} \to \mathcal{K}$ of Diag($\mathcal{K}$) are **bisimilar** if there exists a set $\mathcal{R}$ of triples $(i, \eta, j)$ called a **bisimulation** where $i$ is an object of $\mathcal{I}$, $j$ an object of $\mathcal{J}$ and $\eta : F(i) \xrightarrow{\cong} G(j)$ an isomorphism of $\mathcal{K}$ such that the following conditions hold:

1. For every $i \in \text{Obj}(\mathcal{I})$, there exists $(i, \eta, j) \in \mathcal{R}$ and similarly for every object $j \in \text{Obj}(\mathcal{J})$, there exists $(i, \eta, j) \in \mathcal{R}$.
2. For every triple $(i, \eta, j)$ of $\mathcal{R}$ and every map $\phi : i \to i'$ of $\mathcal{I}$, there exists a triple $(i', \eta', j')$ of $\mathcal{R}$ and a map $\psi : j \to j'$ of $\mathcal{J}$ such that there is the commutative diagram of $\mathcal{K}$

\[
\begin{array}{ccc}
F(i) & \xrightarrow{\eta} & G(j) \\
\downarrow{F(\phi)} & & \downarrow{G(\psi)} \\
F(i') & \xrightarrow{\eta'} & G(j')
\end{array}
\]

and symmetrically, for every triple $(i, \eta, j)$ of $\mathcal{R}$ and every map $\psi : j \to j'$ of $\mathcal{J}$, there exists a triple $(i', \eta', j')$ of $\mathcal{R}$ and a map $\phi : i \to i'$ of $\mathcal{I}$ such that there is the commutative diagram of $\mathcal{K}$

\[
\begin{array}{ccc}
F(i) & \xrightarrow{\eta} & G(j) \\
\downarrow{F(\phi)} & & \downarrow{G(\psi)} \\
F(i') & \xrightarrow{\eta'} & G(j')
\end{array}
\]

5.2. Definition. Let $F : \mathcal{I} \to \mathcal{K}$ and $G : \mathcal{J} \to \mathcal{K}$ be two objects of Diag($\mathcal{K}$). A map $(f, \mu) : F \to G$ is **open** if $f : \mathcal{I} \to \mathcal{J}$ is surjective on objects, if every map $f(i) \to j'$ lifts to a morphism $i \to j$ (in particular $f(j) = j'$) and finally if $\mu : F \Rightarrow G.f$ is a natural isomorphism.

5.3. Proposition. [6, Theorem 2] Two objects $F : \mathcal{I} \to \mathcal{K}$ and $G : \mathcal{J} \to \mathcal{K}$ of Diag($\mathcal{K}$) are bisimilar if and only if they are related by a span of open maps.

Let $\mathcal{M}$ be a model category. We denote by $\mathcal{h} : \mathcal{M} \to \text{Ho}(\mathcal{M})$ the canonical functor from the model category to its homotopy category.

5.4. Definition. Let $F : \mathcal{I} \to \mathcal{M}$ and $G : \mathcal{J} \to \mathcal{M}$ be two objects of Diag($\mathcal{M}$). A map $(f, \mu) : F \to G$ is open up to homotopy if the map $(\mathcal{h}.f, \mu) : \mathcal{h}.F \to \mathcal{h}.G$ of Diag($\text{Ho}(\mathcal{M})$) is open. The diagrams $F : \mathcal{I} \to \mathcal{M}$ and $G : \mathcal{J} \to \mathcal{M}$ are **bisimilar up to homotopy** if the diagram $\mathcal{h}.F : \mathcal{I} \to \text{Ho}(\mathcal{M})$ and $G : \mathcal{J} \to \text{Ho}(\mathcal{M})$ are bisimilar.

5.5. Proposition. If two diagrams $F : \mathcal{I} \to \mathcal{M}$ and $G : \mathcal{J} \to \mathcal{M}$ of Diag($\mathcal{M}$) are related by a span of maps which are open up to homotopy, then the diagrams $F : \mathcal{I} \to \mathcal{M}$ and $G : \mathcal{J} \to \mathcal{M}$ are bisimilar up to homotopy.

**Proof.** Let $F : \mathcal{I} \to \mathcal{M}$ and $G : \mathcal{J} \to \mathcal{M}$ be two objects of Diag($\mathcal{M}$) which are related by a span of maps which are open up to homotopy. This means that there exists a diagram $H$ of Diag($\mathcal{M}$) and a span $F \leftarrow H \to G$ in Diag($\mathcal{M}$) such that the span $\mathcal{h}.F \leftarrow \mathcal{h}.H \to \mathcal{h}.G$ is a span of open maps in Diag($\text{Ho}(\mathcal{M})$). Thus the diagrams
\( \mathbf{h}.F : \mathbb{I} \to \mathbf{h}(\mathcal{M}) \) and \( \mathbf{h}.G : \mathbb{J} \to \mathbf{h}(\mathcal{M}) \) are bisimilar by Proposition 5.3. This means that the diagrams \( F : \mathbb{I} \to \mathcal{M} \) and \( G : \mathbb{J} \to \mathcal{M} \) are bisimilar up to homotopy. □

The converse is not true in general. Indeed, suppose that \( F : \mathbb{I} \to \mathcal{M} \) and \( G : \mathbb{J} \to \mathcal{M} \) are bisimilar up to homotopy. Using Proposition 5.3, we can only conclude the existence of a diagram \( H : \mathbb{K} \to \mathbf{Ho}(\mathcal{M}) \) and of a span of open maps \( \mathbf{h}.F \leftarrow H \to \mathbf{h}.G \) in \( \text{Diag}(\mathbf{Ho}(\mathcal{M})) \).

6. Natural system associated with a general multipointed d-space

After [2, Section 1], the category of factorizations of a small category \( \mathcal{C} \), denoted by \( \mathcal{F}(\mathcal{C}) \) has for objects the morphisms of \( \mathcal{C} \) and for morphisms the extensions of the morphisms of \( \mathcal{C} \). This means that a morphisms from \( f : X \to Y \) to \( f' : X' \to Y' \) is a pair of morphisms \( (u : X' \to X, v : Y \to Y') \) such that there is the commutative square

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{u} & & \downarrow{v} \\
X' & \xleftarrow{f'} & Y'.
\end{array}
\]

Let \( \mathcal{C} \) be a small category. Let \( \mathcal{D} \) be another category. A natural system of objects of \( \mathcal{D} \) on \( \mathcal{C} \) is a functor \( \mathcal{F}(\mathcal{C}) \to \mathcal{D} \).

6.1. Definition. Let \( X \) be a directed space. The category of traces of \( X \), denoted by \( \overrightarrow{T}(X) \), has for objects the points of \( X \) and the set of maps \( \overrightarrow{T}(X)(a,b) \) from \( a \in X \) to \( b \in X \) is the set of traces \( \langle \gamma \rangle \) of directed paths \( \gamma \) going from \( a \) to \( b \), i.e. the set of directed paths from \( a \) to \( b \) up to reparametrization by a map of \( \mathcal{M}(1,1) \). The composition of traces, denoted by \( * \), is induced by the normalized composition of directed paths, i.e. \( \langle \gamma \rangle * \langle \gamma' \rangle = \langle \gamma *_{N} \gamma' \rangle \). It is strictly associative. The mapping \( X \mapsto \overrightarrow{T}(X) \) induces a functor

\[
\overrightarrow{T} : \text{dTop} \longrightarrow \text{Cat}
\]

from the categories of directed spaces to the one of small categories.

Every set \( \overrightarrow{T}(X)(a,b) \) is equipped with the quotient topology in \( \text{Top} \) of the \( \Delta \)-kelleyfi-cation of the compact-open topology by the equivalence relation induced by the identifications \( \gamma \sim \gamma \phi \) for all directed paths \( \gamma \) from \( a \) to \( b \) and all maps \( \phi \in \mathcal{M}(1,1) \).

After [4, Section 6.4], we associate with any directed space \( X \) a natural system

\[
\overrightarrow{NT}(X) : \mathcal{F}(\overrightarrow{T}(X)) \longrightarrow \text{Top}
\]

of topological spaces on \( \overrightarrow{T}(X) \) as follows. The topological space \( \overrightarrow{NT}(X)(\langle \gamma \rangle) \) is by definition the topological space \( \overrightarrow{T}(X)(\gamma(0), \gamma(1)) \). The image of an extension of traces \( \langle \alpha * - * \beta \rangle \) is the continuous map from \( \overrightarrow{T}(X)(\gamma(0), \gamma(1)) \) to \( \overrightarrow{T}(X)(\alpha(0), \beta(1)) \) which takes \( \langle \Gamma \rangle \) to \( \langle \alpha \rangle * \langle \Gamma \rangle * \langle \beta \rangle \). The mapping \( X \mapsto \overrightarrow{NT}(X) \) induces a well-defined functor

\[
\overrightarrow{NT} : \text{dTop} \longrightarrow \text{Diag}(\text{Top})
\]

from the category of directed spaces to that of all small diagrams of topological spaces: see [4, Section 6.4] for further details.
6.2. Notation. Using Theorem 3.6, we extend the functors \( \overrightarrow{T} : d\text{Top} \to \text{Cat} \) and \( \overrightarrow{N}T : d\text{Top} \to \text{Diag}(\text{Top}) \) to functors

\[
\overrightarrow{T} : \text{MdTop} \to \text{Cat} \\
\overrightarrow{N}T : \text{MdTop} \to \text{Diag}(\text{Top})
\]

by setting \( \overrightarrow{T}(X) = \overrightarrow{T}(\text{Sp}(X)) \) and \( \overrightarrow{N}T(X) = \overrightarrow{N}T(\text{Sp}(X)) \) for all multipointed \( d \)-spaces \( X \).

7. FROM DIRECTED PATHS TO TRACES

This section recalls an important fact about the passage from directed paths to traces, i.e. directed paths up to reparametrization. Proposition 7.1 is used in the proofs of Proposition 8.7, Proposition 8.8, Proposition 8.9 and Proposition 8.12 for which the point is to verify that some obvious continuous bijections are actually homeomorphisms. It is not automatic even in the setting of \( \Delta \)-generated spaces since there exists a continuous bijection between Hausdorff \( \Delta \)-generated spaces which is a homotopy equivalence and which is not a homeomorphism: consider the 1-dimensional sphere \( S^1 \), the discretization \( (S^1)^\delta \) and the map between unreduced cones \( C((S^1)^\delta) \to C(S^1) \) [24].

A flow \( X \) is a small enriched semicategory. Its set of objects (preferably called states) is denoted by \( X^0 \) and the space of morphisms (preferably called execution paths) from \( \alpha \) to \( \beta \) is denoted by \( \mathbb{P}_{\alpha,\beta}X \) (e.g. [13, Definition 10.1]). For any topological space \( Z \), the flow \( \text{Glob}(Z) \) is the flow having two states 0 and 1 and such that the only nonempty space of execution paths, when \( Z \) is nonempty, is \( \mathbb{P}_{0,1}\text{Glob}(Z) = Z \).

There is a unique functor

\[
\text{cat} : \text{MdTop} \to \text{Flow}
\]

from the category of multipointed \( d \)-spaces to the category of flows taking a multipointed \( d \)-space \( X \) to the unique flow \( \text{cat}(X) \) such that \( \text{cat}(X)^0 = X^0 \) and such that \( \mathbb{P}_{\alpha,\beta}\text{cat}(X) \) is the quotient of the space of execution paths \( \mathbb{P}_{\alpha,\beta}^\text{top}X \) by the equivalence relation generated by the reparametrization, the composition of \( \text{cat}(X) \) being the composition of traces described in Definition 6.1.

The functor \( \text{cat} : \text{MdTop} \to \text{Flow} \) is not a left adjoint by a proof similar to the proof of [11, Theorem 7.3]. Since both \( \text{MdTop} \) and \( \text{Flow} \) are locally presentable, this implies that \( \text{cat} : \text{MdTop} \to \text{Flow} \) is not colimit-preserving.

However, the point is that, sometimes, the functor \( \text{cat} : \text{MdTop} \to \text{Flow} \) commutes with colimits. Proposition 7.1 should have been put in [17]: it is an omission.

7.1. Proposition. Consider a pushout diagram of multipointed \( d \)-spaces of the form

\[
\begin{array}{ccc}
\text{Glob}^\text{top}(S^{n-1}) & \to & A \\
\downarrow & & \downarrow \\
\text{Glob}^\text{top}(D^n) & \to & B
\end{array}
\]
with a cellular and \( n \geq 0 \). Then there is a pushout diagram of flows

\[
\begin{array}{ccc}
\text{Glob}(S^{n-1}) & \longrightarrow & \text{cat}(A) \\
\downarrow & & \downarrow \\
\text{Glob}(D^n) & \longrightarrow & \text{cat}(B).
\end{array}
\]

**Sketch of proof.** The argument is expounded in a slightly different context in [14, Corollary 8.12]. To save the reader having to read [14], we outline it. The pushout diagram of multipointed \( d \)-spaces gives rise using [17, Corollary 7.4] to a pushout diagram of Moore flows (\( M^M \) is some right adjoint from multipointed \( d \)-spaces to Moore flows)

\[
\begin{array}{ccc}
M^M(\text{Glob}^{\text{top}}(S^{n-1})) & \longrightarrow & M^M(A) \\
\downarrow & & \downarrow \\
M^M(\text{Glob}^{\text{top}}(D^n)) & \longrightarrow & M^M(B).
\end{array}
\]

It is not necessary to recall the definitions of a Moore flow and of the functor \( M^M \) from multipointed \( d \)-spaces to Moore flows. The only point what matters is that there exists a left adjoint \( M_0 \) from Moore flows to flows by [13, Theorem 10.7] and that, by [17, Theorem 7.11], there is the isomorphism of functors \( \text{cat} \cong M_0 M^M \). We obtain the pushout diagram of flows

\[
\begin{array}{ccc}
\text{cat}(\text{Glob}^{\text{top}}(S^{n-1})) & \longrightarrow & \text{cat}(A) \\
\downarrow & & \downarrow \\
\text{cat}(\text{Glob}^{\text{top}}(D^n)) & \longrightarrow & \text{cat}(B).
\end{array}
\]

It remains to observe that \( \text{cat}(\text{Glob}^{\text{top}}(Z)) = \text{Glob}(Z) \) for any topological space \( Z \) to complete the proof. \( \square \)

**8. Natural systems associated with a cellular multipointed \( d \)-space**

**8.1. Notation.** In the whole section, \( X \) stands for a cellular multipointed \( d \)-space.

Let \( c \) be a globular cell of \( X \). The center of \( c \), denoted by \( \langle c \rangle \), is equal to \( c \) for \( c \in X^0 \) and is the point \( \hat{g}_c((0, \ldots, 0), 1/2) \) when \( c \) is a globular cell of dimension \( \geq 1 \), where \( \hat{g}_c : \text{Glob}^{\text{top}}(D^{\dim(c)}) \to X \) is the attaching map of \( c \). Note that for \( \alpha \in X^0 \), \( \langle \alpha \rangle \) denotes either the center of \( \alpha \), i.e. \( \alpha \), or the trace of the constant directed path equal to \( \alpha \).

**8.2. Proposition.** Let \( c \preceq d \) be two globular cells of \( X \). Then \( \overrightarrow{T}(X)(\langle c \rangle, \langle d \rangle) \) is a singleton and the unique element is denoted by \( \langle c, d \rangle \).

**Proof.** There are two mutually exclusive cases:

(1) \( c = d^- \) and \( \dim(d) \geq 1 \). Let \( \hat{g}_d : \text{Glob}^{\text{top}}(D^{\dim(d)}) \to X \) be the attaching map of \( d \). The unique element of \( \overrightarrow{T}(X)(\langle c \rangle, \langle d \rangle) \) is the trace \( t \mapsto \hat{g}_d((0, \ldots, 0), t/2) \).
8.3. Proposition. Let \(c\) be a globular cell of \(X\) with \(\dim(c) \geq 1\). Let \(u, v \in c \cup \{c^-, c^+\}\) such that there exists a directed path from \(u\) to \(v\) and such that \(\{u, v\} \neq \{c^-, c^+\}\). Then there is a unique trace, denoted by \(\tau_{u,v}\), from \(u\) to \(v\) inside \(c \cup \{c^-, c^+\}\). Moreover, the hypothesis \(\{u, v\} \neq \{c^-, c^+\}\) cannot be removed if \(\dim(c) \geq 2\).

Proof. The case \(\dim(c) = 1\) is obvious. We assume now \(\dim(c) \geq 2\). Let

\[
\hat{g} : \text{Glob}^{\text{top}}(D^{\dim(c)}) \to X
\]

be the attaching map of the globular cell \(c\). Since \(\{u, v\} \neq \{c^-, c^+\}\), either \(u = \hat{g}(z, t)\) or \(v = \hat{g}(z, t)\) for some \(z \in D^{\dim(c)} \setminus S^{\dim(c)-1}\) and some \(t \in [0,1]\). Assume the first case

\[
u = \hat{g}(z, t),\]

the other case being similar. Since there is a directed path from \(u\) to \(v\), this implies that

\[
v = \hat{g}(z, t')\]

for some \(t \leq t' \leq 1\). The directed path from \(u\) to \(v\) are of the form \(\hat{g}t_\delta \phi\) where \(\phi : [0,1] \to [t,t']\) is non-decreasing and surjective. Moreover the point \(z \in D^{\dim(c)} \setminus S^{\dim(c)-1}\) is unique. Hence the proof of the main statement is complete. The hypothesis \(\{u, v\} \neq \{c^-, c^+\}\) is necessary: if \(u = c^-\) and \(v = c^+\), then all execution paths \(\hat{g}t_\delta\) for \(z\) running over \(D^{\dim(c)} \setminus S^{\dim(c)-1}\) goes from \(c^-\) to \(c^+\). See Figure 3 for an illustration.

8.4. Proposition. Let \(c\) be a globular cell of \(X\). Let \(x \in c\). Then there is a unique trace, denoted by \(\tau_x\) from \(c^-\) to \(c^+\) passing by \(x\). One has \(\tau_x = \tau_x^c \ast \tau_x^c\) where \(\tau_x^c\) is the unique trace going from \(c^-\) to \(x\) and where \(\tau_x^c\) is the unique trace going from \(x\) to \(c^+\). In particular, one has \(\tau_x(c) = \tau_x(c) = \langle c \rangle\) if \(\dim(c) = 0\) and \(\tau_x(c) = \langle c^-, c, c^+\rangle\), \(\tau_x^c(c) = \langle c^-, c \rangle\) and \(\tau_x^c(c) = \langle c, c^+\rangle\) if \(\dim(c) \geq 1\).

Proof. There is nothing to prove for \(\dim(c) = 0\). Assume that \(\dim(c) \geq 1\). Let \(\hat{g} : \text{Glob}^{\text{top}}(D^{\dim(c)}) \to X\) be the attaching map of the globular cell \(c\). Since \(x \in c\), there exists a unique \(z \in D^{\dim(c)} \setminus S^{\dim(c)-1}\) and a unique \(t \in [0,1]\) such that \(x = \hat{g}(z, t)\). The unique trace \(\tau_x\) is \(\langle \hat{g}t_\delta \rangle\). One necessarily has \(\tau_x^c = \langle \hat{g}t_\delta(t \mapsto (t/2))\rangle\) and \(\tau_x^c = \langle \hat{g}t_\delta(t \mapsto (t/2 + 1/2))\rangle\) (see Figure 3).

8.5. Proposition. Let \(c\) be a globular cell of \(X\) with \(\dim(c) \geq 1\). Let \(x, y \in c\). If there exists a directed path from \(x\) to \(y\), then \(\tau_x = \tau_y\).

Proof. Let \(\hat{g} : \text{Glob}^{\text{top}}(D^{\dim(c)}) \to X\) be the attaching map of the globular cell \(c\). Since \(x \in c\), there exists a unique \(z \in D^{\dim(c)} \setminus S^{\dim(c)-1}\) and a unique \(t \in [0,1]\) such that \(x = \hat{g}(z, t)\). Since \(y \in c\) and since there exists a directed path from \(x\) to \(y\), one has \(x = \hat{g}(z, t')\) for some \(t \leq t' < 1\). Thus \(\tau_x = \tau_y = \langle \hat{g}t_\delta \rangle\).
8.6. **Lemma.** Let $\gamma$ be a directed path of $X$. There are five mutually exclusive cases:
(1) $\gamma(0), \gamma(1) \in X^0$;
(2) $\gamma(0) \notin X^0, \gamma(1) \in X^0$;
(3) $\gamma(0) \in X^0, \gamma(1) \notin X^0$;
(4) $\gamma(0) \notin X^0, \gamma(1) \notin X^0$ and $\text{dt}(\gamma(0)) \neq \text{dt}(\gamma(1))$;
(5) $\gamma(0) \notin X^0, \gamma(1) \notin X^0$ and $\text{dt}(\gamma(0)) = \text{dt}(\gamma(1))$.

The first four cases correspond to the situation $\text{dt}(\gamma(0)) \neq \text{dt}(\gamma(1))$ or $\gamma(0) = \gamma(1) \in X^0$.
The fifth case corresponds to the situation $\text{dt}(\gamma(0)) = \text{dt}(\gamma(1)) = c$ and $\dim(c) \geq 1$.

**Proof.** Obvious. $\Box$

8.7. **Proposition.** Let $c$ be a globular cell of dimension greater than 1. Let $x \in c$. Let $\alpha \in X^0$. Then there is the homeomorphism

$$
\begin{align*}
\tilde{T}(X)(c^+, \alpha) & \cong \tilde{T}(X)(x, \alpha) \\
\tau & \mapsto \tau_x^* \tau
\end{align*}
$$

**Proof.** Consider the pushout diagram of multipointed $d$-spaces

$$
\begin{array}{c}
\text{Glob}^{\text{lop}}(S^{-1}) \xrightarrow{0 \rightarrow \tau} \{x\} \sqcup X \\
\downarrow \quad \downarrow \\
\text{Glob}^{\text{lop}}(D^0) \xrightarrow{\text{cat}(\{x\} \sqcup X)} X. \\
\end{array}
$$

The key observation is that there is the homeomorphism

$$
\tilde{P}(X)(x, \alpha) \cong \text{cat}^{\text{lop}}_{\tau, \alpha} X
$$

between the space of directed paths from $x$ to $\alpha$ in $X$ and the space of execution paths from $\tau$ to $\alpha$ in $X$. By Proposition 7.1, we obtain the pushout diagram of flows

$$
\begin{array}{c}
\text{Glob}(S^{-1}) \xrightarrow{0 \rightarrow \tau} \text{cat}(\{x\} \sqcup X) \quad \Delta \\
\downarrow \quad \downarrow \\
\text{Glob}(D^0) \xrightarrow{\hat{g}} \text{cat}(X). \\
\end{array}
$$
Figure 4. \(|U| = [0, 1] \times [0, 1], \ \ U^0 = \{0\} \times [0, 1] \cup \{(x, x) \mid x \in [0, 1]\},
\ \ \ \ P^\text{top}_{(0,0),(t,t)} U = M(1,1) \text{ for all } t \in [0,1],
\ \ \ \ P^\text{top}_{(0,0),(0,0)} U = \{(0,0)\} \text{ and } P^\text{top}_{\alpha,\beta} U = \emptyset
\ \ \ \text{otherwise, there is no composable execution paths.}

From the homeomorphism \(\overrightarrow{T}(X)(x, \alpha) \cong P^\text{top}_{\pi,\alpha} X\), we deduce the homeomorphism
\[(TE) \ \ \ \overrightarrow{T}(X)(x, \alpha) \cong P_{\pi,\alpha} \text{cat}(X).\]
We can now conclude. First, assume that \(c^+ \neq \alpha\). Then we obtain the sequence of
homeomorphisms
\[
\overrightarrow{T}(X)(x, \alpha) \cong P_{\pi,\alpha} \text{cat}(X) \\
\cong P_{\pi, c^+} \text{cat}(X) \times P_{c^+, \alpha} \text{cat}(X) \\
\cong P_{c^+, \alpha} \text{cat}(X) \\
= \overrightarrow{T}(X)(c^+, \alpha),
\]
the first homeomorphism by (TE), the second homeomorphism by the commutativity of
\(A\) and by general results about enriched semicategories, the third homeomorphism since
\(P_{\pi, c^+} \text{cat}(X)\) is a singleton, and finally the equality since \(c^+ \neq \alpha\). Now assume that \(c^+ = \alpha\).
Then we obtain the sequence of homeomorphisms
\[
\overrightarrow{T}(X)(x, c^+) \cong P_{\pi, c^+} \text{cat}(X) \\
\cong \{\hat{g}(0)\} \sqcup \{\hat{g}(0)\} \times P_{c^+, c^+} \text{cat}(X) \\
\cong \overrightarrow{T}(X)(c^+, c^+),
\]
the first homeomorphism by (TE), the second homeomorphism by the commutativity of
\(A\) and since the execution paths from \(x\) to \(c^+\) in the flow \(\text{cat}(X)\) consists of the execution
path \(\hat{g}(0)\) and all compositions \(\hat{g}(0) \ast \gamma\) where \(\gamma\) is an execution path of \(\text{cat}(X)\) from \(c^+\)
to itself, and the third homeomorphisms because the space of traces from \(c^+\) to itself contains
also the constant path \(c^+\) which is in a distinct path-connected component because \(X\) is
cellular. \(\Box\)

The last sentence does require for \(X\) to be cellular. Figure 4 shows an example of a
multipointed \(d\)-space \(U\) containing a sequence of non-constant execution paths converging
to a constant execution path.

23
8.8. **Proposition.** Let $c$ be a globular cell of dimension greater than 1. Let $x \in c$. Let $\alpha \in X^0$. Then there is the homeomorphism

$$\begin{aligned}
\tau & \mapsto \begin{cases} 
\tau \ast \tau_x^- \ast \tau_x^-
\end{cases}
\end{aligned}
$$

Proof. We start from the pushout diagram of multipointed $d$-spaces

\[\text{Glob}^{\text{op}}(S^{-1}) \rightrightarrows \{\tau\} \sqcup X \quad \text{Glob}^{\text{op}}(D^0) \sqcup X.\]

The key observation is that there is the homeomorphism

\[\bar{P}(X)(\alpha, x) \cong P^{\text{op}}_{\alpha, \tau} X\]

between the space of directed paths from $\alpha$ to $x$ in $X$ and the space of execution paths from $\alpha$ to $\tau$ in $X$. The rest of the proof is similar to the one of Proposition 8.7. It makes use of Proposition 7.1. \(\square\)

8.9. **Proposition.** Let $c \neq d$ be two globular cells of dimension greater than 1. Let $x \in c$ and $y \in d$. there are the homeomorphisms

$$\begin{aligned}
\tau & \mapsto \begin{cases} 
\tau \ast \tau_x^+ \ast \tau_y^-
\end{cases}
\end{aligned}
$$

Proof. We start from the pushout diagram of multipointed $d$-spaces

\[\text{Glob}^{\text{op}}(S^{-1}) \sqcup \text{Glob}^{\text{op}}(S^{-1}) \rightrightarrows \{\tau, \gamma\} \sqcup X \quad \text{Glob}^{\text{op}}(D^0) \sqcup \text{Glob}^{\text{op}}(D^0) \sqcup X.\]

where $g$ takes the states 0, 1 of the left-hand copy of $\text{Glob}^{\text{op}}(S^{-1})$ to $\tau$ and $c^+$ respectively and the states 0, 1 of the right-hand copy of $\text{Glob}^{\text{op}}(S^{-1})$ to $d^-$ and $\gamma$ respectively. The key observation is then that there is the homeomorphism

\[\bar{P}(X)(x, y) \cong P^{\text{op}}_{\tau, \gamma} X\]

between the space of directed paths from $x$ to $y$ in $X$ and the space of execution paths from $\tau$ to $\gamma$ in $X$. The rest of the proof is similar to the one of Proposition 8.7. It makes use of Proposition 7.1. \(\square\)

8.10. **Proposition.** Let $\gamma$ be a directed path of $X$. Assume that $\text{dt}(\gamma(0)) \neq \text{dt}(\gamma(1))$ or $\gamma(0) = \gamma(1) \in X^0$. Then there is the homeomorphism

$$\begin{aligned}
\tau & \mapsto \begin{cases} 
\tau \ast \tau_{\gamma(0)}^+ \ast \tau_{\gamma(1)}^-
\end{cases}
\end{aligned}
$$

Proof. By Lemma 8.6, there are four mutually exclusive cases.
(1) $\gamma(0), \gamma(1) \in X^0$. Then there is the equality
$$\vec{T}(X)(\gamma(0), \gamma(1)) = \vec{T}(X)(\text{dt}(\gamma(0))^+, \text{dt}(\gamma(1))^-)$$
because $\gamma(0) = \text{dt}(\gamma(0))^+ \in X^0$ and $\gamma(1) = \text{dt}(\gamma(1))^- \in X^0$.

(2) $\gamma(0) \notin X^0$, $\gamma(1) \in X^0$. Then $\dim(\text{dt}(\gamma(0))) \geq 1$ and one has
$$\vec{T}(X)(\gamma(0), \gamma(1)) \cong \vec{T}(X)(\text{dt}(\gamma(0))^+, \gamma(1)) = \vec{T}(X)(\text{dt}(\gamma(0))^+, \text{dt}(\gamma(1))^-)$$
the homeomorphism by Proposition 8.7 and the equality because $\gamma(1) = \text{dt}(\gamma(1))^- \in X^0$.

(3) $\gamma(0) \in X^0$, $\gamma(1) \notin X^0$. Then $\dim(\text{dt}(\gamma(1))) \geq 1$ and one has
$$\vec{T}(X)(\gamma(0), \gamma(1)) \cong \vec{T}(X)(\gamma(0), \text{dt}(\gamma(1))^-) = \vec{T}(X)(\text{dt}(\gamma(0))^+, \text{dt}(\gamma(1))^-)$$
the homeomorphism by Proposition 8.8 and the equality because $\gamma(0) = \text{dt}(\gamma(0))^+ \in X^0$.

(4) $\gamma(0) \notin X^0$, $\gamma(1) \notin X^0$, $\text{dt}(\gamma(0)) \neq \text{dt}(\gamma(1))$. Then one has $\dim(\text{dt}(\gamma(0))) \geq 1$ and $\dim(\text{dt}(\gamma(1))) \geq 1$. We obtain the homeomorphism
$$\vec{T}(X)(\gamma(0), \gamma(1)) \cong \vec{T}(X)(\text{dt}(\gamma(0))^+, \text{dt}(\gamma(1))^-)$$
by Proposition 8.9. \hfill \Box

8.11. Proposition. Let $\gamma$ be a directed path of $X$. Assume that $\text{dt}(\gamma(0)) \neq \text{dt}(\gamma(1))$ or $\gamma(0) = \gamma(1) \in X^0$. Then there is the homeomorphism
$$\begin{cases} 
\vec{T}(X)(\text{dt}(\gamma(0))^+, \text{dt}(\gamma(1))^-) \cong \vec{T}(X)((\text{dt}(\gamma(0))), (\text{dt}(\gamma(1)))) \\
\tau \mapsto \tau_{\gamma(0), \gamma(1)} 
\end{cases}$$

Proof. We apply Proposition 8.10 to the directed path $(\text{dt}(\gamma))$. \hfill \Box

8.12. Proposition. Let $\gamma$ be a directed path of $X$. Assume that $\text{dt}(\gamma(0)) = \text{dt}(\gamma(1)) = c$ and $\dim(c) \geq 1$. Then there is the homeomorphism
$$\begin{cases} 
\{\tau_{\gamma(0), \gamma(1)}\} \sqcup \vec{T}(X)(c^+, c^-) \cong \vec{T}(X)(\gamma(0), \gamma(1)) \\
\tau_{\gamma(0), \gamma(1)} \mapsto \tau_{\gamma(0), \gamma(1)} \\
\tau \mapsto \tau_{\gamma(0), \gamma(1)} \ast \tau * \tau_{\gamma(0), \gamma(1)} 
\end{cases}$$

Proof. We start from the pushout diagram of multipointed $d$-spaces
$$\begin{array}{ccc}
\text{Glob}^{top}(S^{-1}) \sqcup \text{Glob}^{top}(S^{-1}) & \xrightarrow{g} & \{\gamma_0, \gamma_1\} \sqcup X \\
\downarrow & & \downarrow \\
\text{Glob}^{top}(D^0) \sqcup \text{Glob}^{top}(D^0) & \xrightarrow{X} & \\
\end{array}$$
where $g$ takes the states $0, 1$ of the left-hand copy of $\text{Glob}^{top}(S^{-1})$ to $\gamma_0$ and $c^+$ respectively, and the states $0, 1$ of the right-hand copy of $\text{Glob}^{top}(S^{-1})$ to $c^-$ and $\gamma_1$ respectively. The key observation is that the space of directed paths from $\gamma(0)$ to $\gamma(1)$ in $X$ is the disjoint sum of the space of directed paths from $\gamma(0)$ to $\gamma(1)$ inside the globular cell $c$ and of the space of directed paths from $\gamma(0)$ to $\gamma(1)$ exiting the globular cell $c$ via $c^+$ and returning to
the globular $c$, necessarily via $c^-$, to come back to $\gamma(1)$. We obtain the homeomorphisms

$$P(X)(\gamma(0), \gamma(1)) \cong \{\gamma(0)\} \cup P_{\gamma_0, \gamma_1}$$

if $\gamma(0) = \gamma(1)$ and

$$P(X)(\gamma(0), \gamma(1)) \cong P_{\gamma_0, \gamma_1} \cup P_{\gamma_0, \gamma_1}$$

otherwise. The rest of the proof is similar to the one of Proposition 8.7. It makes use of Proposition 7.1. \qed

8.13. Proposition. Let $\gamma$ be a directed path of $X$. Assume that $\text{dt}(\gamma(0)) = \text{dt}(\gamma(1)) = c$ and $\text{dim}(c) \geq 1$. Then there is the homeomorphism

$$\{\langle c \rangle \} \cup \overrightarrow{\text{Tr}}(X)(c^+, c^-) \cong \overrightarrow{\text{Tr}}(X)(\langle \text{dt}(\gamma(0)) \rangle, \langle \text{dt}(\gamma(1)) \rangle)$$

$$\langle c \rangle \mapsto \langle c \rangle$$

$$\tau \mapsto \langle c, c^+ \rangle * \tau * \langle c^-, c \rangle$$

Proof. We apply Proposition 8.12 to the directed path $\langle \text{dt}(\gamma) \rangle$. \qed

8.14. Corollary. Let $\gamma$ be a directed path of $X$. There is a homeomorphism

$$\overrightarrow{\text{NT}}(X)(\langle \gamma \rangle) \cong \overrightarrow{\text{Tr}}(X)(\langle \text{dt}(\gamma(0)) \rangle, \langle \text{dt}(\gamma(1)) \rangle).$$

Proof. It is a consequence of Proposition 8.10, Proposition 8.11, Proposition 8.12 and Proposition 8.13. \qed

8.15. Definition. The category of discrete traces of $X$, denoted by $\overrightarrow{\text{Tr}}(X)$, has for objects the globular cells of $X$ and a morphism from a globular cell $c$ to a globular cell $d$ is a discrete trace $[c_1, \ldots, c_n]$ with $c_1 = c$ and $c_n = d$.

We can associate with any cellular multipointed $d$-space $X$ a natural system

$$\overrightarrow{\text{NT}}_d(X) : \mathcal{F}(\overrightarrow{\text{Tr}}_d(X)) \rightarrow \text{Top}$$

of topological spaces on $\overrightarrow{\text{Tr}}_d(X)$ as follows. The topological spaces $\overrightarrow{\text{NT}}_d(X)([c_1, \ldots, c_n])$ is by definition $\overrightarrow{\text{Tr}}(X)(\langle c_1 \rangle, \langle c_n \rangle)$. The image of an extension of traces $\langle a_1, \ldots, a_m \rangle * \langle b_1, \ldots, b_n \rangle$ is the continuous map from $\overrightarrow{\text{Tr}}(X)(\langle a_m \rangle, \langle b_1 \rangle)$ to $\overrightarrow{\text{Tr}}(X)(\langle a_1 \rangle, \langle a_m \rangle, \langle b_1 \rangle)$ which takes $\langle \Gamma \rangle$ to $\langle a_1, \ldots, a_m \rangle * \langle \Gamma \rangle * \langle b_1, \ldots, b_n \rangle$.

Theorem 8.16 is the globular analogue of [4, Theorem 28 page 157].

8.16. Theorem. There exists a map of natural systems

$$f : \overrightarrow{\text{NT}}(X) \rightarrow \overrightarrow{\text{NT}}_d(X)$$

which is open up to homotopy.

Proof. The mapping $\text{dt}(-)$ induces a functor from $\overrightarrow{\text{Tr}}(X)$ to $\overrightarrow{\text{Tr}}_d(X)$. The image of a point $x \in |X|$ is the unique globular cell $\text{dt}(x)$ containing $x$ and the image of a trace $\langle \gamma \rangle$ is the discrete trace $\text{dt}(\gamma)$.

This functor induces a functor from $\mathcal{F}(\overrightarrow{\text{Tr}}(X))$ to $\mathcal{F}(\overrightarrow{\text{Tr}}_d(X))$ which takes a trace $\langle \gamma \rangle$ to its discrete trace $\text{dt}(\gamma)$. The latter functor is surjective on objects since

$$\text{dt}(\langle c_1, \ldots, c_n \rangle) = [c_1, \ldots, c_n].$$

We have to prove that it lifts extension of traces.
Let $\gamma$ be a directed path of $X$ with $dt(\gamma) = [c_1, \ldots, c_n]$. Let $c_0 \preceq c_1$. There are two mutually exclusive cases: (1) $\dim(c_0) = 0$, $\dim(c_1) \geq 1$, $c_0 = c_1^-$ (2) $\dim(c_0) \geq 1$, $\dim(c_1) = 0$, $c_0^+ = c_1$.

(1) $\dim(c_0) = 0$, $\dim(c_1) \geq 1$, $c_0 = c_1^-$. This means that $c_0 = c_1^-$ and $\gamma(0) \in c_1$. In this case, one has

$$dt(\langle \gamma(0) \rangle) = [c_0, c_1, \ldots, c_n].$$

(2) $\dim(c_0) \geq 1$, $\dim(c_1) = 0$, $c_0^+ = c_1$. This means that $\gamma(0) = c_0^+ = c_1$. In this case one has

$$dt(\langle c_0, c_1 \rangle) = [c_0, c_1, \ldots, c_n].$$

The treatment of the extension of traces on the other side, i.e. a globular cell $c_{n+1}$ such that $c_n \preceq c_{n+1}$ is similar.

Let $\gamma$ be a directed path of $X$. Then there are the homeomorphisms between topological spaces

$$\overrightarrow{NT}(X)(\langle \gamma \rangle) \cong \overrightarrow{T}(X)(\langle dt(\gamma(0)) \rangle, \langle dt(\gamma(1)) \rangle) = \overrightarrow{NT}_d(X)(dt(\gamma)).$$

The left-hand homeomorphism by Corollary 8.14 and the right-hand equality by definition of $\overrightarrow{NT}_d(X)$. It remains to prove that for any extension of traces $\langle \alpha * - * \beta \rangle$, there is a square of topological spaces which is commutative up to homotopy

$$\overrightarrow{NT}(X)(\langle \gamma \rangle) \cong \overrightarrow{NT}_d(X)(dt(\gamma)) \cong \overrightarrow{NT}(X)(\langle \alpha \ast \langle \gamma \rangle \ast \langle \beta \rangle \rangle) \cong \overrightarrow{NT}_d(X)(dt(\alpha \ast \gamma \ast \beta)).$$

The latter can be decomposed in two squares of topological spaces as follows:

$$\overrightarrow{NT}(X)(\langle \gamma \rangle) \cong \overrightarrow{NT}_d(X)(dt(\gamma)) \cong \overrightarrow{NT}(X)(\langle \alpha \ast \langle \gamma \rangle \rangle) \cong \overrightarrow{NT}_d(X)(dt(\alpha \ast \gamma)).$$

It suffices to prove e.g. the commutativity up to homotopy of the top one $R$. The proof of the commutativity of the bottom one $S$ is similar.

Let $dt(\gamma) = [c_1, \ldots, c_n]$. It suffices to make the proof for a directed path $\alpha$ such that $dt(\alpha) = [c_0]$, which implies $c_0 \preceq c_1$. Remember that $c_1 = dt(\gamma(0))$ and $c_n = dt(\gamma(1))$. The sentence $c_0 \preceq c_1$ means that $c_0 \neq c_1$ and either $c_0 = c_1^-$ or $c_0^+ = c_1$. By Lemma 8.6, there are two mutually exclusive cases: (a) $c_1 \neq c_n$ or $c_1 = c_n \in X^0$; (b) $c_1 = c_n$ and $\dim(c_1) = \dim(c_n) \geq 1$. If $c_0 = c_1^-$, then $\dim(c_1) \geq 1$.

There are therefore three mutually exclusive cases: (1) $c_0 = c_1^-$ and $c_1 \neq c_n$ and $\dim(c_1) \geq 1$; (2) $c_0 = c_1^-$ and $c_1 = c_n$ and $\dim(c_1) \geq 1$; (3) $c_0^+ = c_1$. We are going to need
to subdivide the third case in two subcases (3a) $c_0^+ = c_1$ and $c_0 \neq c_n$ and (3b) $c_0^+ = c_1$ and $c_0 = c_n$. Remember that in all cases, $\gamma(0) \in c_1$ and $\gamma(1) \in c_n$ by Theorem 4.10.

(1) $c_0 = c_1^+$ and $c_1 \neq c_n$ and $\dim(c_1) \geq 1$. In this case, one has $c_0 \in X^0$. One has $\widetilde{\mathcal{N}}T(X)((\gamma)) \cong \widetilde{T}(X)(c_1^+, c_n^-)$ by Proposition 8.10. The composite map

$$\Psi : \widetilde{\mathcal{N}}T(X)((\gamma)) \xrightarrow{\cong} \widetilde{\mathcal{N}}d(X)([c_1, \ldots, c_n]) \xrightarrow{\sim} \widetilde{\mathcal{N}}d(X)([c_0, c_1, \ldots, c_n]) \xrightarrow{\cong} \widetilde{\mathcal{N}}T(X)((\alpha) \ast (\gamma))$$

takes $\Gamma \in \widetilde{T}(X)(c_1^+, c_n^-)$ to $\langle c_0, c_1, c_1^+ \rangle \ast \Gamma$. The direct route

$$\widetilde{\mathcal{N}}T(X)((\gamma)) \cong \widetilde{T}(X)(c_1^+, c_n^-) \rightarrow \widetilde{\mathcal{N}}T(X)((\alpha) \ast (\gamma)) \cong \widetilde{T}(X)(c_0^+, c_n^-)$$

takes $\Gamma \in \widetilde{T}(X)(c_1^+, c_n^-)$ to $\tau_{\gamma(0)} \ast \Gamma$. Since the traces $\langle c_0, c_1, c_1^+ \rangle$ and $\tau_{\gamma(0)}$ are the traces of two execution paths from $c_0$ to $c_1^+$ inside the globular cell $c$, they are in the same path-connected component. Thus the top square $\square$ is commutative up to homotopy.

(2) $c_0 = c_1^+$ and $c_1 = c_n$ and $\dim(c_1) \geq 1$. In this case, one has $c_0 \in X^0$. One has

$$\widetilde{\mathcal{N}}T(X)((\gamma)) \cong \{\tau_{\gamma(0)}, \gamma(1)\} \sqcup \widetilde{T}(X)(c_1^+, c_n^-)$$

by Proposition 8.12. Consider the composite map

$$\Psi : \widetilde{\mathcal{N}}T(X)((\gamma)) \xrightarrow{\cong} \widetilde{\mathcal{N}}d(X)([c_1, \ldots, c_n]) \xrightarrow{\sim} \widetilde{\mathcal{N}}d(X)([c_0, c_1, \ldots, c_n]) \xrightarrow{\cong} \widetilde{\mathcal{N}}T(X)((\alpha) \ast (\gamma))$$

One has

$$\Psi : \tau_{\gamma(0)}, \gamma(1) \xrightarrow{\sim} \langle \tau_{\gamma(0)}, \gamma(1) \rangle = \langle c_1 \rangle \xrightarrow{\sim} \langle c_0, c_1 \rangle \xrightarrow{\sim} \langle c_0 \rangle$$

The direct route

$$\widetilde{\mathcal{N}}T(X)((\gamma)) \cong \{\tau_{\gamma(0)}, \gamma(1)\} \sqcup \widetilde{T}(X)(c_1^+, c_1^-) \rightarrow \widetilde{\mathcal{N}}T(X)((\alpha) \ast (\gamma)) \cong \widetilde{T}(X)(c_0^+, c_1^-)$$

takes $\tau_{\gamma(0)}, \gamma(1)$ to $\langle c_0 \rangle$ and $\Gamma \in \widetilde{T}(X)(c_1^+, c_1^-)$ to $\tau_{\gamma(0)} \ast \Gamma$. Since the traces $\langle c_0, c_1, c_1^+ \rangle$ and $\tau_{\gamma(0)}$ are the traces of two execution paths from $c_0$ to $c_1^+$ which are in the same path-connected component, we conclude that the top square $\square$ is commutative up to homotopy.

(3a) $c_0^+ = c_1$ and $c_0 \neq c_n$. In this case, one has $\dim(c_0) \geq 1$ and $c_1 \in X^0$. One has $\widetilde{\mathcal{N}}T(X)((\gamma)) \cong \widetilde{T}(X)(c_1^+, c_n^-)$ by Proposition 8.10. The composite map

$$\Psi : \widetilde{\mathcal{N}}T(X)((\gamma)) \xrightarrow{\cong} \widetilde{\mathcal{N}}d(X)([c_1, \ldots, c_n]) \xrightarrow{\sim} \widetilde{\mathcal{N}}d(X)([c_0, c_1, \ldots, c_n]) \xrightarrow{\cong} \widetilde{\mathcal{N}}T(X)((\alpha) \ast (\gamma))$$

is a homeomorphism since $c_0^+ = c_1^+$. The direct route

$$\widetilde{\mathcal{N}}T(X)((\gamma)) \cong \widetilde{T}(X)(c_1^+, c_n^-) \xrightarrow{\cong} \widetilde{\mathcal{N}}T(X)((\alpha) \ast (\gamma)) \cong \widetilde{T}(X)(c_0^+, c_n^-)$$

is a homeomorphism as well since $c_0^+ = c_1^+$. We conclude that the top square $\square$ is strictly commutative.

(3b) $c_0^+ = c_1$ and $c_0 = c_n$. In this case, one has $\dim(c_0) \geq 1$ and $c_1 \in X^0$. One still has $\widetilde{\mathcal{N}}T(X)((\gamma)) \cong \widetilde{T}(X)(c_1^+, c_n^-)$ by Proposition 8.10. However, by Proposition 8.13, the
Figure 5. Example of a globular subdivision of $c$

topological space $\overrightarrow{NT}_d(X)([c_0, c_1, \ldots, c_n])$ has an additional path-connected component $\{\langle c_0 \rangle \}$ which is not in the image of the map $\overrightarrow{NT}_d(X)([c_1, \ldots, c_n]) \to \overrightarrow{NT}_d(X)([c_0, c_1, \ldots, c_n])$.

Thus the composite map

$$
\Psi : \overrightarrow{NT}(X)(\langle \gamma \rangle) \cong \overrightarrow{NT}_d(X)(\langle c_0, c_1, \ldots, c_n \rangle) \to \overrightarrow{NT}_d(X)(\langle c_0, c_1, \ldots, c_n \rangle) \cong \overrightarrow{NT}(X)(\langle \alpha \rangle * \langle \gamma \rangle)
$$

is not anymore a homeomorphism, unlike in (3a). The direct route

$$
\overrightarrow{NT}(X)(\langle \gamma \rangle) \cong \overrightarrow{T}(X)(c^+_1, c^-_n) \to \overrightarrow{NT}(X)(\langle \alpha \rangle * \langle \gamma \rangle) \cong \overrightarrow{T}(X)(c^+_0, c^-_n)
$$

is not a homeomorphism either. But the top square $\mathbb{R}$ is still strictly commutative. \qed

9. INVARIANCE UNDER GLOBULAR SUBDIVISION

9.1. Definition. [19, Definition 4.10] A map of multipointed $d$-spaces $f : X \to Y$ is a **globular subdivision** if both $X$ and $Y$ are cellular and if $f$ induces a homeomorphism between the underlying topological spaces of $X$ and $Y$.

The terminology used in [19, Definition 4.10] is $T$-homotopy equivalence. The reason of the terminology of globular subdivision is that it is a globular analogue of the cubical subdivision studied in [4].

9.2. Proposition. There exists a map of multipointed $d$-spaces $f : X \to Y$ inducing a homeomorphism $f : |X| \to |Y|$ such that $\overrightarrow{Sp}(f) : \overrightarrow{Sp}(X) \to \overrightarrow{Sp}(Y)$ is not an isomorphism of directed spaces.

Proof. Let $X = ([0, 1], \{0, 1\})$ and $Y = \overrightarrow{T}^{top}$. Consider the map of multipointed $d$-spaces $f : X \to Y$ induced by the identity of $[0, 1]$. The directed space $\overrightarrow{Sp}(X)$ contains only constant paths whereas the directed space $\overrightarrow{Sp}(Y)$ contains all continuous maps going from $a$ to $b$ with $a \leq b$. \qed

9.3. Theorem. Let $f : X \to Y$ be a map of multipointed $d$-spaces between two cellular multipointed $d$-spaces $X$ and $Y$. The following two conditions are equivalent:

1. The map $f : X \to Y$ is a globular subdivision.
2. The map of directed spaces $\overrightarrow{Sp}(f) : \overrightarrow{Sp}(X) \to \overrightarrow{Sp}(Y)$ is an isomorphism.
**Proof.** The implication (2) ⇒ (1) is obvious. Let us prove the implication (1) ⇒ (2).

Assume (1). Since $f : |X| \to |Y|$ is one-to-one, it induces a one-to-one map from the set of directed paths $d(X)$ of $X$ to the set of directed paths $d(Y)$ of $Y$. It remains to prove that $f$ induces a surjective map from $d(X)$ to $d(Y)$.

Consider at first the case of a directed path of $Y$ which is a regular execution path of the form $\gamma = \hat{g} \delta_z$ with $\text{Carrier}(\gamma) = [c']$ for some globular cell $c'$ of $Y$ with corresponding attaching map $\hat{g} : \text{Glob}^{\text{top}}(D^{\dim(c')}) \to X$ and for some $z' \in D^{\dim(c')} \backslash S^{\dim(c')-1}$. Then $\gamma(1/2) \notin Y^0$. Thus $f^{-1}(\gamma(1/2)) \notin X^0$. Consider the globular cell of $X$ of dimension greater than 1

$$c = dt\left(f^{-1}(\gamma(1/2))\right)$$

containing $f^{-1}(\gamma(1/2))$. Write $\tilde{g} : \text{Glob}^{\text{top}}(D^{\dim(c)}) \to X$ for the corresponding attaching map. Then

$$f^{-1}(\gamma(1/2)) = \tilde{g}(z, t)$$

for some $z \in D^{\dim(c)} \backslash S^{\dim(c)-1}$ and some $t \in [0, 1]$. The execution path $f \tilde{g} \delta_z$ of $Y$ contains $\gamma(1/2)$. One has $\gamma(0) = \hat{g} \delta_z(0) = (f \hat{g} \delta_z)(t_0) \in Y^0$ and $\gamma(1) = \hat{g} \delta_z(1) = (f \hat{g} \delta_z)(t_1) \in Y^0$ for some real numbers $t_0, t_1$ such that $0 \leq t_0 < t < t_1 \leq 1$. Consider the directed path $\Gamma$ of $Y$ defined by

$$\Gamma(u) = f(\tilde{g}(z, t_0 + (t_1 - t_0)u)).$$

It goes from $\Gamma(0) = f(\tilde{g}(z, t_0)) = \gamma(0)$ to $\Gamma(1) = f(\tilde{g}(z, t_1)) = \gamma(1)$. Moreover, one has

$$\Gamma\left(\frac{t - t_0}{t_1 - t_0}\right) = f(\tilde{g}(z, t)) = \gamma(1/2).$$

The directed path $\Gamma$ being regular since $f$ is a bijective, there is the inclusion

$$\Gamma([0, 1]) \subset dt(\gamma(1/2)) = c'.$$

This means that $\Gamma$ is a directed path from $\gamma(0)$ to $\gamma(1)$ inside the globular cell $c'$ of $Y$ passing by $\gamma(1/2)$. This implies that $\Gamma$ is an execution path of $Y$ and that there exists $\phi \in \mathcal{M}(1, 1)$ such that

$$\Gamma = \hat{g} \delta_z \psi' = \gamma \phi.$$

Since both $\Gamma$ and $\gamma$ are regular paths, $\phi$ is actually a homeomorphism from $[0, 1]$ to itself by Proposition 2.8. We obtain

$$\gamma = f\left(\tilde{g} \delta_z \left(u \mapsto t_0 + (t_1 - t_0)\phi^{-1}(u)\right)\right)$$

Since the map $u \mapsto t_0 + (t_1 - t_0)\phi^{-1}(u) \in I(1)$, we have proved that $\gamma$ is the image by $f$ of a directed path of $X$.

Using Theorem 4.6, we deduce that any execution path of $Y$ is the image by $f$ of a directed path of $X$. Finally, by Theorem 4.9, we obtain that any directed path of $Y$ is the image by $f$ of a directed path of $X$. \qed

From Figure 5, it seems that for any globular subdivision $f : X \to Y$, any $\alpha \in Y^0 \backslash X^0$ is on a directed path between two states of $f(X^0)$ and that this directed path is locally unique up to reparametrization. Indeed, for such a state $\alpha$, the point $f^{-1}(\alpha)$ belongs to a unique globular cell $dt(f^{-1}(\alpha))$ of $X$. There is unique trace $\mathcal{T}_{f^{-1}(\alpha)}$ going from $dt(f^{-1}(\alpha))^{-}$ to $dt(f^{-1}(\alpha))^+$. And $\alpha$ belongs to $f(dt(f^{-1}(\alpha)))$.

9.4. **Theorem.** Let $f : X \to Y$ be a globular subdivision. Then the natural systems $\overrightarrow{NT}_d(X)$ and $\overrightarrow{NT}_d(Y)$ are bisimilar up to homotopy.

**Proof.** It is a consequence of Proposition 5.5, Theorem 8.16 and Theorem 9.3. \hfill \Box

10. **NATURAL SYSTEMS AND Q-MODEL STRUCTURE**

A model category is a bicomplete category $\mathcal{M}$ equipped with a class of cofibrations $C$, a class of fibrations $F$ and a class of weak equivalences $W$ such that: 1) $W$ is closed under retract and satisfies two-out-of-three property, 2) the pairs $(C, W \cap F)$ and $(C \cap W, F)$ are functorial weak factorization systems. We refer to [22, Chapter 1] and to [21, Chapter 7] for the basic notions about general model categories.

The purpose of this section is to show the incompatibility of the notion of bisimilar natural systems and the model structures studied so far on multipointed $d$-spaces.

The **q-model structure** of multipointed $d$-spaces is the unique combinatorial model structure such that

$$\{\text{Glob}^{\text{top}}(S^{n-1}) \subset \text{Glob}^{\text{top}}(D^n) \mid n \geq 0\} \cup \{C : \varnothing \to \{0\}, R : \{0, 1\} \to \{0\}\}$$

is the set of generating cofibrations, the maps between globes being induced by the closed inclusions $S^{n-1} \subset D^n$, and such that

$$\{\text{Glob}^{\text{top}}(D^n \times \{0\}) \subset \text{Glob}^{\text{top}}(D^{n+1}) \mid n \geq 0\}$$

is the set of generating trivial cofibrations, the maps between globes being induced by the closed inclusions $(x_1, \ldots, x_n) \mapsto (x_1, \ldots, x_n, 0)$. The weak equivalences are the maps of multipointed $d$-spaces $f : X \to Y$ inducing a bijection $f^0 : X^0 \cong Y^0$ and a weak homotopy equivalence $\mathbb{P}^{\text{top}}f : \mathbb{P}^{\text{top}}X \to \mathbb{P}^{\text{top}}Y$ and the fibrations are the maps of multipointed $d$-spaces $f : X \to Y$ inducing a q-fibration $\mathbb{P}^{\text{top}}f : \mathbb{P}^{\text{top}}X \to \mathbb{P}^{\text{top}}Y$ of topological spaces.

A construction of this model structure is given in [16, Theorem 6.16] for a more specific version of multipointed $d$-spaces. The argument still works here because it relies on the use of the Quillen path object argument in [16, Theorem 6.14] applied to the right adjoint from multipointed $d$-spaces to topological graphs which forgets the composition and the reparametrization of execution paths.

10.1. **Proposition.** There exists a trivial q-fibration $f : A \to B$ between two cellular multipointed $d$-spaces such that the map from $\overrightarrow{NT}(f) : \overrightarrow{NT}(A) \to \overrightarrow{NT}(B)$ is not open up to homotopy.
Proof. Consider the multipointed $d$-space $B$ depicted in Figure 7. Consider the multipointed $d$-space $A$, depicted in Figure 6, and obtained by the pushout diagram which adds a globular cell $c$ of dimension 2:

$$\text{Glob}^{\text{top}}(\{0\}) \xrightarrow{0 \cdot d_1 \times d_2 \times d_3} B$$

$$\text{Glob}^{\text{top}}([0,1]) \xrightarrow{\tilde{g}} A$$

There is a map of multipointed $d$-space $f : A \to B$ which is a trivial $q$-fibration and which intuitively crushes the 2-dimensional globe $c$ depicted in Figure 6. The point is that $\overrightarrow{NT}(A)(\{c\})$ is contractible whereas $\overrightarrow{NT}(B)((d_1, d_1^+, d_2, d_2^+, d_3))$ has two distinct path-connected components. Therefore the map $\overrightarrow{NT}(A)(\{c\}) \to \overrightarrow{NT}(B)((d_1, d_1^+, d_2, d_2^+, d_3))$ is not a weak homotopy equivalence.

We want to conclude this work by reproducing the same phenomenon with a directed space without globes. Consider the directed space $X$ depicted in Figure 8 which contains $B$ and the gray rectangle above $B$. The directed paths of $X$ in the gray rectangle are by definition all horizontal paths which are non-decreasing with respect to the direction of time. The retract $r : X \to B$ of the gray rectangle on the line $d_4$ does not induce an open map $\overrightarrow{NT}(r) : \overrightarrow{NT}(X) \to \overrightarrow{NT}(B)$ since $\overrightarrow{T}(u, v)$ is contractible whereas $\overrightarrow{T}(u', v')$ contains two path-connected components. The situation is different with the directed space $X'$ depicted in Figure 9 having the same underlying topological space as $X$ and such that the directed paths in the gray rectangle are all paths (not only the horizontal
Figure 9. The directed space $X'$: the directed paths are non-decreasing with respect to the time line but not necessarily horizontal ones) which are non-decreasing with respect to the direction of time. In that case, the map $\overrightarrow{NT}(r') : \overrightarrow{NT}(X') \to \overrightarrow{NT}(B)$ is an open map.

The difference in behavior of the retracts $\overrightarrow{NT}(r) : \overrightarrow{NT}(X) \to \overrightarrow{NT}(B)$ and $\overrightarrow{NT}(r') : \overrightarrow{NT}(X') \to \overrightarrow{NT}(B)$ seems to suggest that the cause of the incompatibility between the q-model structure of multipointed $d$-spaces and the notion of bisimilar natural systems is that the cellular multipointed $d$-spaces contain too few execution paths.
