Types as Resources for Classical Natural Deduction

Delia Kesner and Pierre Vial
IRIF (CNRS and Université Paris-Diderot), France

Abstract
We define two resource aware typing systems for the $\lambda\mu$-calculus based on non-idempotent intersection and union types. The non-idempotent approach provides very simple combinatorial arguments based on decreasing measures of type derivations to characterize head and strongly normalizing terms. Moreover, typability provides upper bounds for the length of head-reduction sequences and maximal reduction sequences.

1 Introduction

A few years after Griffin [22] observed that Feilleisen’s C operator can be typed with the double-negation elimination, Parigot [32] made a major step in extending the Curry-Howard from intuitionistic to classical logic by proposing the $\lambda\mu$-calculus as a simple term notation for classical natural deduction proofs. Other calculi were proposed since then, as for example Curien-Herbelin’s $\lambda\tilde{\mu}$-calculus [11] based on classical sequent calculus.

Simple types are known to be unable to type some normalizing term, for instance the normal form $\Delta = \lambda x.x x$. Intersection types, pioneered by Coppo and Dezani [9, 10], extend simple types by resorting to a new constructor $\cap$ for types, allowing the assignment of a type of the form $((\sigma \Rightarrow \sigma) \cap \sigma) \Rightarrow \sigma$ to the term $\Delta$. The intuition behind a term $t$ of type $\tau_1 \cap \tau_2$ is that $t$ has both types $\tau_1$ and $\tau_2$. The intersection operator $\cap$ is to be understood as idempotent $(\sigma \cap \sigma = \sigma)$, commutative $(\sigma \cap \tau = \tau \cap \sigma)$, and associative $((\sigma \cap \tau) \cap \delta = \sigma \cap (\tau \cap \delta))$ laws. Among other applications, intersection types have been used as a behavioural tool to reason about several operational and semantical properties of programming languages. For example, a $\lambda$-term/program $t$ is strongly normalizing/terminating if and only if $t$ can be assigned a type in an appropriate intersection type assignment system.

This technology turns out to be a powerful tool to reason about qualitative properties of programs, but not about quantitative ones. Indeed, e.g. there is a type system assigning a type to a term $t$ if and only if $t$ is head normalizing, but the type derivations give no information about the number of head-reduction steps needed to head-normalize $t$, because of idempotency. In constrast, after the pioneering works of Gardner [19] and Kfoury [27], D. de Carvalho [14, 15] established a relation between the size of a typing derivation in a non-idempotent intersection type system for the lambda-calculus and the head/weak-normalization execution time of head/weak-normalizing lambda-terms, respectively. Non-idempotent types have recently received a lot of attention in the domain of semantics of programming languages from a quantitative perspective (see for example [6]), notably because they are closely related to Girard’s translation of intuitionistic logic into linear logic (according to which $A \Rightarrow B$ becomes $!A \rightarrow B$).
The case of the $\lambda\mu$-calculus: The non-idempotent intersection and union types for lambda-mu-calculus that we present in this article can be seen as a quantitative refinement of Girard’s translation of classical logic into linear logic. Different qualitative and/or quantitative models for classical calculi were proposed in [34, 37, 39, 3], thus limiting the characterization of operational properties to head-normalization. Intersection and union types were also studied in the framework of classical logic [30, 36, 28, 17], but no work addresses the problem from a quantitative perspective. Type-theoretical characterization of strong-normalization for classical calculi were provided both for $\lambda\mu$ [38] and $\lambda\mu\bar\mu$-calculus [17], but the (idempotent) typing systems do not allow to construct decreasing measures for reduction, thus a resource aware semantics cannot be extracted from those interpretations. Combinatorial strong normalization proofs for the $\lambda\mu$-calculus were proposed for example in [12], but they do not provide any explicit decreasing measure, and their use of structural induction on simple types does not work anymore with intersection types, which are more powerful than simple types as they do not only ensure termination but also characterize it. Different small step semantics for classical calculi were developed in the framework of neededness [4, 33], without resorting to any resource aware semantical argument.

In this paper we define a resource aware type system for the $\lambda\mu$-calculus based on non-idempotent intersection and union types. The non-idempotent approach provides very simple combinatorial arguments, only based on a decreasing measure, to characterize head and strongly normalizing terms by means of typability. In the well-known case of the $\lambda$-calculus, the measure $sz(\Pi)$ of a derivation $\Pi$ is simply given by the number of its nodes. This approach cannot be straightforwardly adapted to $\lambda\mu$, and we need now to take into account the structure (multiplicity and size) of certain types appearing in the types derivations.

By lack of space we cannot provide in this submission all the proofs of our results, but we refer the interested reader to the extended detailed version available at [26].

2 The $\lambda\mu$-Calculus

This section gives the syntax (Sec. 2.1) and the operational semantics (Sec. 2.2) of the $\lambda\mu$-calculus [32]. But before this we first introduce some preliminary general notions of rewriting that will be used all along the paper, and that are applicable to any system $\mathcal{R}$. We denote by $\rightarrow_{\mathcal{R}}$ the (one-step) reduction relation associated to system $\mathcal{R}$. We write $\rightarrow_{\mathcal{R}}^n$ for the reflexive-transitive closure of $\rightarrow_{\mathcal{R}}$, and $\rightarrow_{\mathcal{R}}^n$ for the composition of $n$-steps of $\rightarrow_{\mathcal{R}}$, thus $t \rightarrow_{\mathcal{R}}^n u$ denotes a finite $\mathcal{R}$-reduction sequence of length $n$ from $t$ to $u$. A term $t$ is in $\mathcal{R}$-normal form, written $t \in \mathcal{R}$-nf, if there is no $t'$ s.t. $t \rightarrow_{\mathcal{R}} t'$; and $t$ has an $\mathcal{R}$-normal form iff there is $t' \in \mathcal{R}$-nf such that $t \rightarrow_{\mathcal{R}}^* t'$. A term $t$ is said to be strongly $\mathcal{R}$-normalizing, written $t \in SN(\mathcal{R})$, iff there is no infinite $\mathcal{R}$-sequence starting at $t$.

2.1 Syntax

We consider a countable infinite set of variables $x, y, z, \ldots$ (resp. continuation names $\alpha, \beta, \gamma, \ldots$). The set of objects $(O_{\lambda\mu})$, terms $(T_{\lambda\mu})$ and commands $(C_{\lambda\mu})$ of the $\lambda\mu$-calculus are given by the following grammars:

(objects) \quad o \quad ::= \quad t \mid c

terms) \quad t, u, v \quad ::= \quad x \mid \lambda x.t \mid tu \mid \mu \alpha.c
(commands) \quad c \quad ::= \quad [\alpha]t

We write $T_{\lambda}$ for the set of $\lambda$-terms. We abbreviate $(\ldots((tu_1)u_2)\ldots u_n)$ as $tu_1 \ldots u_n$ or $t\overline{u}$ when $n$ is clear from the context. The grammar extends $\lambda$-terms with two new constructors:
commands $[\alpha]t$ and $\mu$-abstractions $\mu \alpha.c$. Free and bound variables of objects are defined as expected, in particular $fv(\mu \alpha.c) := fv(c)$ and $fv([\alpha]t) := fv(t)$. Free names of objects are defined as expected, in particular $fn(\mu \alpha.c) := fn(c) \setminus \{\alpha\}$ and $fn([\alpha]t) := fn(t) \cup \{\alpha\}$.

Bound names are defined accordingly.

We work with the standard notion of $\alpha$-conversion i.e. renaming of bound variables and names, thus for example $[\delta](\mu \alpha.[\alpha](\lambda x.x)) \equiv [\delta][\mu \beta.[\beta](\lambda y.y))z$. Substitutions are (finite) functions from variables to terms specified by $\{x_1/u_1, \ldots, x_n/u_n\}$ ($n \geq 0$). Application of the substitution $\sigma$ to the object $o$, written $o \sigma$, may require $\alpha$-conversion in order to avoid capture of free variables/names, and it is defined as expected. Replacements are (finite) functions from names to terms specified by $\{\alpha_1//u_1, \ldots, \alpha_n//u_n\}$ ($n \geq 0$). Intuitively, the operation $\{\alpha//u\}$ passes the term $u$ as an argument to any command of the form $[\alpha]t$.

Formally, the application of the replacement $\Sigma$ to the object $o$, written $o \Sigma$, may require $\alpha$-conversion in order to avoid the capture of free variables/names, and is defined as:

\[
\begin{align*}
  x([\alpha//u]) & := x \\
  ([\alpha]t)([\alpha//u]) & := [\alpha](t{\alpha//u})u \\
  ([\gamma]t)([\alpha//u]) & := [\gamma](t{\alpha//u})u \\
  (\mu \gamma.c)([\alpha//u]) & := \mu \gamma.c{\alpha//u}
\end{align*}
\]

For example, if $I = \lambda z.z$, then $(x(\mu \alpha[y])(\lambda z.x))\{x/I\} = I(\mu \alpha[y])(\lambda z.z I)$, and $[\alpha]x(\mu \beta.[\alpha]y)\{\alpha//I\} = [\alpha](x\mu \beta.[\alpha]y I)I$.

### 2.2 Operational Semantics

The $\lambda \mu$-calculus is given by the set of objects introduced in Sec. 2.1 and the reduction relation $\Rightarrow_{\lambda \mu}$, which is the closure by all contexts of the following rewriting rules:

\[
\begin{align*}
  (\lambda x.t)u & \Rightarrow_{\beta} t{x/u} \\
  (\mu \alpha.c)u & \Rightarrow_{\mu} \mu \alpha.c{\alpha//u}
\end{align*}
\]

defined by means of the substitution and replacement application notions given in Sec. 2.1. A redex is a term of the form $(\lambda x.t)u$ or $(\mu \alpha.c)u$. We write $t \Rightarrow_{\lambda \mu} t'$ (or simply $t \Rightarrow t'$) to denote the closure by all contexts of the reduction relation generated by the previous set of rewriting rules.

A head-context is a context defined by the following grammar:

\[
\begin{align*}
  \mathcal{HO} & ::= \mathcal{HT} | \mathcal{HC} \\
  \mathcal{HT} & ::= \Box t_1 \ldots t_n \ (n \geq 0) | \lambda x.\mathcal{HT} | \mu \alpha.\mathcal{HC} \\
  \mathcal{HC} & ::= [\alpha]\mathcal{HT}
\end{align*}
\]

A head-normal form is an object of the form $\mathcal{HO}[x]$, where $x$ is any variable replacing the constant $\Box$. Thus for example $\mu \alpha.[\beta]\lambda y.x(\lambda z.z)$ is a head-normal form. An object $o \in \mathcal{O}_{\lambda \mu}$ is said to be head-normalizing, written $o \in \mathcal{HN}(\lambda \mu)$, if $o \Rightarrow_{\lambda \mu}^* \ o'$, for some head-normal form $o'$. Remark that $o \in \mathcal{HN}(\lambda \mu)$ does not imply $o \in \mathcal{SN}(\lambda \mu)$ while the converse necessarily holds. We write $\mathcal{HN}(\lambda)$ and $\mathcal{SN}(\lambda)$ when $t$ is restricted to be a $\lambda$-term and the reduction system is restricted to the $\beta$-reduction rule.

A redex $r$ in a term of the form $t := \mathcal{HO}[r]$ is called the head-redex of $t$. The reduction step $t \Rightarrow_{\lambda \mu} t'$ contracting the head-redex of $t$ is called head-reduction. The reduction sequence composing head-reduction steps until head-normal form is called the head-strategy. If the head-strategy starting at $o$ terminates, then $o \in \mathcal{HN}(\lambda \mu)$, while the converse will be stated later (cf. Thm. 7).

A typical example of expressivity in the $\lambda \mu$-calculus is the control operator [22] $\text{call-cc} := \lambda y.\mu \alpha.[\alpha]y(\lambda x.\mu \beta.[\alpha]x)$ which gives raise to the following reduction sequence:
call-cc \( t u_1 \ldots u_n \rightarrow_\beta (\mu\alpha.[\alpha](\lambda x.\mu\beta.[\alpha]x))u_1 \ldots u_n \rightarrow_\mu (\mu\alpha.[\alpha](\lambda x.\mu\beta.[\alpha]x)u_1)u_2 \ldots u_n \rightarrow_\mu^* (\mu\alpha.[\alpha](\lambda x.\mu\beta.[\alpha]x)u_1 \ldots u_n)u_1 \ldots u_n \)

A reduction step \( o \rightarrow o' \) is said to be erasing if \( o = (\lambda x.u)v \) and \( x \notin \text{fv}(u) \), or \( o = (\mu\alpha.c)u \) and \( \alpha \notin \text{fn}(c) \). Thus e.g. \( (\lambda x.z)y \rightarrow z \) and \( (\mu\alpha.[\beta]x)I \rightarrow_\mu \mu\alpha.[\beta]x \) are erasing steps. A reduction step \( o \rightarrow o' \) which is not erasing is called non-erasing. Reduction is stable by substitution and replacement. More precisely, if \( o \rightarrow o' \), then \( o\{x/u\} \rightarrow o'\{x/u\} \) and \( o\{\alpha//u\} \rightarrow o'\{\alpha//u\} \). These stability properties give the following corollary.

\[ \textbf{Corollary 1.} \text{ If } o\{x/u\} \in SN(\lambda_\mu) \text{ (resp. } o\{\alpha//u\} \in SN(\lambda_\mu)) \text{, then } o \in SN(\lambda_\mu). \]

### 3 Quantitative Type Systems for the \( \lambda \)-Calculus

As mentioned before, our results rely on typability of \( \lambda_\mu \)-terms in suitable systems with non-idempotent types. Since the \( \lambda_\mu \)-calculus embeds the \( \lambda \)-calculus, we start by recalling the well-known [19, 14, 7] quantitative type systems for \( \lambda \)-calculus, called here \( H_\lambda \) and \( S_\lambda \). We then reformulate them, using a different syntactical formulation, resulting in the typing systems \( H'_\lambda \) and \( S'_\lambda \) that are the formalisms we adopt in Sec. 4 for \( \lambda_\mu \).

We start by fixing a countable set of base types \( a, b, c, \ldots \), then we introduce two different categories of types specified by the following grammars:

\[
\begin{align*}
(\text{Intersection Types}) & \quad \mathcal{I} & := & \left[ \sigma_{k}\right]_{k \in K} \\
(\text{Types}) & \quad \sigma, \tau & := & a \mid I \Rightarrow \sigma
\end{align*}
\]

An intersection type \( \left[ \sigma_{k}\right]_{k \in K} \) is a multiset that can be understood as a type \( \sigma_1 \land \ldots \land \sigma_n \), where \( \land \) is associative and commutative, but non-idempotent. The non-deterministic choice operation \( \_^* \) is defined on intersection types as follows:

\[
\left[ \sigma_{k}\right]_{k \in K}^* := \begin{cases} 
\tau & \text{if } K = \emptyset \text{ and } \tau \text{ is any arbitrary type} \\
\sigma_k & \text{if } K \neq \emptyset
\end{cases}
\]

Variable assignments (\( \Gamma \)) are functions from variables to intersection types. The domain of \( \Gamma \) is given by \( \text{dom}(\Gamma) := \{ x \mid \nexists \Gamma(x) \neq [] \} \), where \( [] \) is the empty intersection type. We write \( x_1 : \mathcal{I}_1, \ldots, x_n : \mathcal{I}_n \) for the assignment of domain \( \{ x_1, \ldots, x_n \} \) mapping each \( x_i \) to \( \mathcal{I}_i \). When \( x \notin \text{dom}(\Gamma) \), then \( \Gamma(x) \) stands for \( [] \). We write \( \Gamma \land \Gamma' \) for \( x \mapsto \Gamma(x) + \Gamma'(x) \), where + is multiset union, and \( \text{dom}(\Gamma \land \Gamma') = \text{dom}(\Gamma) \cup \text{dom}(\Gamma') \). We write \( \Gamma \setminus x \) for the assignment defined by \( (\Gamma \setminus x)(x) = [] \) and \( (\Gamma \setminus x)(y) = \Gamma(y) \) if \( y \neq x \).

To present/discuss different typing systems, we consider the following derivability notions. A type judgment is a triple \( \Gamma \vdash t : \sigma \), where \( \Gamma \) is a variable assignment, \( t \) a term and \( \sigma \) a type. A (type) derivation in system \( \mathcal{X} \) is a tree obtained by applying the (inductive) rules of the type system \( \mathcal{X} \). We write \( \Phi_{\mathcal{X}} \Gamma \vdash t : \sigma \) if \( \Phi \) is a type derivation concluding with the type judgment \( \Gamma \vdash t : \sigma \), and just \( \vdash_{\mathcal{X}} \Gamma \vdash t : \sigma \) if there exists \( \Phi \) such that \( \Phi_{\mathcal{X}} \Gamma \vdash t : \sigma \). A term \( t \) is \( \mathcal{X} \)-typable iff there is a derivation in \( \mathcal{X} \) typing \( t \), i.e. if there is \( \Phi \) such that \( \Phi_{\mathcal{X}} \Gamma \vdash t : \sigma \). We may omit the index \( \mathcal{X} \) if the name of the system is clear from the context.

#### 3.1 Characterizing Head \( \beta \)-Normalizing \( \lambda \)-Terms

We discuss in this section typing systems being able to characterize head \( \beta \)-normalizing \( \lambda \)-terms. We first consider system \( H_\lambda \) in Fig. 1, first appearing in [19], then in [14].

Notice that \( K = \emptyset \) in rule \( \to_\emptyset \) allows to type an application \( tu \) without necessarily typing the subterm \( u \). Thus for example, if \( \Omega = (\lambda x.xx)(\lambda x.xx) \), then from the judgment \( x : [\sigma] \vdash x : \sigma \) we can derive \( x : [\sigma] \vdash (\lambda y.x)\Omega : \sigma \).

System \( H_\lambda \) characterizes head \( \beta \)-normalization:
We now discuss typing systems being able to characterize strong \rule{.8em}{.8em} system of \( H \) first consider system \( \beta \). Let \( t \in T_\lambda \). Then \( t \) is \( H_\lambda \)-typable iff \( t \in HN(\lambda) \).

Moreover, the implication typability implies normalization can be shown by simple arithmetical arguments provided by the quantitative flavour of the typing system \( H_\lambda \), in contrast to classical reducibility arguments usually invoked in other cases [20, 29]. Actually, the arithmetical arguments give the following quantitative property:

\( \blacksquare \) \textbf{Lemma 3.} If \( t \) is \( H_\lambda \)-typable with tree derivation \( \Pi \), then the size (number of nodes) of \( \Pi \) gives an upper bound to the length of the head-reduction strategy starting at \( t \).

To reformulate system \( H_\lambda \) in a different way, we now distinguish two sorts of judgments: regular judgments of the form \( \Gamma \vdash t : \sigma \) assign types to terms, and auxiliary judgments of the form \( \Gamma \vdash t : I \) assign intersection types to terms.

An equivalent formulation of system \( H_\lambda \), called \( H'_\lambda \), is given in Fig. 2. There are two inherited forms of type derivations: regular (resp. auxiliary) derivations are those that conclude with regular (resp. auxiliary) judgments. Notice that \( I = \emptyset \) in rule (\( \wedge \)) gives \( \vdash u : [] \) for any term \( u \), e.g. \( \vdash \: [] \), so that one can derive \( x : [\tau] \vdash (\lambda y. x) \Omega : \tau \) in this system. Notice also that systems \( H_\lambda \) and \( H'_\lambda \) are relevant, i.e. they lack weakening. Equivalence between \( H_\lambda \) and \( H'_\lambda \) gives the following result:

\( \blacksquare \) \textbf{Corollary 4.} Let \( t \in T_\lambda \). Then \( t \) is \( H'_\lambda \)-typable iff \( t \in HN(\lambda) \).

Auxiliary judgments turn out to substantially lighten the notations and to make the statements (and their proofs) more readable.

### 3.2 Characterizing Strong \( \beta \)-Normalizing \( \lambda \)-Terms

We now discuss typing systems being able to characterize strong \( \beta \)-normalizing \( \lambda \)-terms. We first consider system \( S_\lambda \) in Fig. 3, which appears in [8] (slight variants appear in [13, 6, 24]). Rule (\( \Rightarrow_\perp \)) forces the erasable arguments (the subterm \( u \)) to be typed, even if the type of \( u \) (i.e. \( \sigma \)) is not being used in the conclusion of the judgment. Thus, in contrast to system \( H_\lambda \), every subterm of a typed term is now typed. System \( S_\lambda \) characterizes strong \( \beta \)-normalization:

\( \blacksquare \) \textbf{Lemma 5.} Let \( t \in T_\lambda \). Then \( t \) is \( S_\lambda \)-typable iff \( t \in SN(\lambda) \).

As before, the implication typability implies normalization can be shown by simple arithmetical arguments provided by the quantitative flavour of the typing system \( S_\lambda \).

An equivalent formulation of system \( S_\lambda \), called \( S'_\lambda \), is given in Fig. 4. As before, we use regular as well as auxiliary judgments. Notice that \( I = \emptyset \) in rule (\( \wedge \)) is still possible,
but derivations of the form $\Gamma \vdash t : []$, representing untyped terms, will never be used. The choice operation $\ast$ (defined at the beginning of Sec. 3) in rule $(\Rightarrow_\ast)$ is used to impose an arbitrary type for an erasable term, i.e. when $t$ has type $[] \Rightarrow \tau$, then $u$ needs to be typed with an arbitrary type $[\sigma]$, thus the auxiliary judgment typing $u$ on the right premise of $(\Rightarrow_\ast)$ cannot assign $[]$ to $u$. This should be understood as a sort of controlled weakening. Here is an example of type derivation in system $S'_\lambda$:

$$\begin{align*}
&x : [\sigma] \vdash x : \sigma \\
&\vdash z : [\tau] \vdash z : \tau \\
&\begin{array}{c}
\Gamma \vdash t : \sigma_k, \Gamma_k \vdash t : [\sigma_k]_{k \in K} \\
\end{array}
\vdash \begin{array}{c}
\begin{array}{c}
\vdash \lambda y. x : [] \Rightarrow \sigma \\
\vdash z : [\tau] \vdash z : [\tau] \\
\end{array}
\end{array}
\vdash x : [\sigma], z : [\tau] \vdash (\lambda y. x) z : \sigma
\end{align*}$$

Since $S_\lambda$ and $S'_\lambda$ are equivalent, we also have:

\begin{itemize}
\item \textbf{Corollary 6.} Let $t \in T_\lambda$. Then $t$ is $S'_\lambda$-typable iff $t \in SN(\lambda)$.
\end{itemize}

### 4 Quantitative Type Systems for the $\lambda_\mu$-Calculus

We present in this section two quantitative systems for the $\lambda_\mu$-calculus, systems $H_{\lambda_\mu}$ (Sec. 4.2) and $S_{\lambda_\mu}$ (Sec. 4.3), characterizing, respectively, head and strong $\lambda_\mu$-normalizing objects. Since $\lambda$-calculus is embedded in the $\lambda_\mu$-calculus, then the starting points to design $H_{\lambda_\mu}$ and $S_{\lambda_\mu}$ are, respectively, $H'_\lambda$ and $S'_\lambda$, introduced in Sec. 3.

#### 4.1 Types

We consider a countable set of base types $a, b, c \ldots$ and the following categories of types:

- (Object Types) $A := C \mid U$
- (Command Type) $C := \#$
- (Union Types) $U, V := (\sigma_k)_{k \in K}$
- (Intersection Types) $I := [\sigma_k]_{k \in K}$
- (Types) $\sigma, \tau := a \mid I \Rightarrow U$

The constant $\#$ is used to type commands, union types to type terms and intersection types to type variables (thus left-hand sides of arrows). Both $[\sigma_k]_{k \in \{1..n\}}$ and $(\sigma_k)_{k \in \{1..n\}}$ can be
seen as multisets, representing, respectively, $\sigma_1 \cap \ldots \cap \sigma_n$ and $\sigma_1 \cup \ldots \cup \sigma_n$, where $\cap$ and $\cup$ are both associative, commutative, but non-idempotent. We may omit the indices in the simplest case: thus $[U]$ and $\langle \sigma \rangle$ denote singleton multisets. We define the operator $\wedge$ (resp. $\vee$) on intersection (resp. union) multiset types by: $[U_{\sigma}]_{k \in K} \wedge [V_{\tau}]_{\ell \in L} := [U_{\sigma}]_{k \in K} \cup [V_{\tau}]_{\ell \in L}$ and $\langle \sigma_k \rangle_{k \in K} \vee \langle \tau_\ell \rangle_{\ell \in L} := \langle \sigma_k \rangle_{k \in K} + \langle \tau_\ell \rangle_{\ell \in L}$, where $+$ always means multiset union. The non-deterministic choice operation $\ast$ is now defined on intersection and union types:

$$
[U]_{k \in K} := \begin{cases} [U] & \text{if } K = \emptyset \text{ and } U \neq \langle \rangle \\
[U]_{k \in K} & \text{if } K \neq \emptyset
\end{cases}
$$

$$
\langle \sigma \rangle_{k \in K} := \begin{cases} \langle \sigma \rangle & \text{if } K = \emptyset \text{ and } \sigma \text{ is any arbitrary blind type} \\
\langle \sigma_k \rangle_{k \in K} & \text{if } K \neq \emptyset
\end{cases}
$$

where a blind type is a type of the form $[\ ] \to \ldots \to [\ ] \to a$. The choice operator for union type is defined so that (1) the empty union cannot be assigned to $\mu$-abstractions (see discussion on the non-emptiness of union-types, page 9) (2) subject reduction is guaranteed in system $H_{\lambda_u}$ for erasing steps $(\mu.a.c)u \to \mu.a.c$ ($a \notin \text{fn}(c)$).

The arity of types and union multiset types is defined by induction: for types $\sigma$, if $\sigma = I \Rightarrow U$, then $\text{ar}(\sigma) := \text{ar}(U) + 1$, otherwise, $\text{ar}(\sigma) := 0$; for union multiset types, $\text{ar}(\langle \sigma_k \rangle_{k \in K}) := \Sigma_{k \in K} \text{ar}(\sigma_k)$. The cardinality of multisets is defined by $|U_k|_{k \in K} = |\langle \sigma_k \rangle_{k \in K}| := |K|$.

**Variable assignments** ($\Gamma$), are, as before, functions from variables to intersection multiset types. Similarly, **name assignments** ($\Delta$), are functions from names to union multiset types. The **domain** of $\Delta$ is given by $\text{dom}(\Delta) := \{ \alpha \mid \Delta(x) \neq \langle \rangle \}$, where $\langle \rangle$ is the empty union multiset. We may write $\emptyset$ to denote the name assignment that associates the empty union type $\langle \rangle$ to every name. When $\alpha \notin \text{dom}(\Delta)$, then $\Delta(x)$ stands for $\langle \rangle$. We write $\Delta \vee \Delta'$ for $\alpha \mapsto \Delta(\alpha) + \Delta'(\alpha)$, where $\text{dom}(\Delta \vee \Delta') = \text{dom}(\Delta) \cup \text{dom}(\Delta')$.

When $\text{dom}(\Gamma)$ and $\text{dom}(\Gamma')$ are disjoint we may write $\Gamma;\Gamma'$ instead of $\Gamma \wedge \Gamma'$. We write $x : [U_k]_{k \in K};\Gamma$, even when $K = \emptyset$, for the following variable assignment $(x : [U_k]_{k \in K};\Gamma)(x) = [U_k]_{k \in K}$ and $(x : [U_k]_{k \in K};\Gamma)(y) = \Gamma(y)$ if $y \neq x$. Similar concepts apply to name assignments, so that $\alpha : \langle \sigma_k \rangle_{k \in K};\Delta$ and $\Delta \parallel \alpha$ are defined as expected.

We now present our typing systems $H_{\lambda_u}$ and $S_{\lambda_u}$, both having regular (resp. auxiliary) judgments of the form $\Gamma \vdash t : U \mid \Delta$ (resp. $\Gamma \vdash t : I \mid \Delta$), together with their respective notions of regular and auxiliary derivations. An important syntactical property they enjoy is that both are syntax directed, i.e. for each (regular/auxiliary) typing judgment $j$ there is a unique typing rule whose conclusion matches the judgment $j$. This makes our proofs much simpler than those arising with idempotent types which are based on long generation lemmas (e.g. [6, 36]).

### 4.2 System $H_{\lambda_u}$

In this section we present a quantitative typing system for $\lambda_u$, called $H_{\lambda_u}$, characterizing head $\lambda_u$-normalization. It can be seen as a first intuitive step to understand the typing system $S_{\lambda_u}$, introduced later in Sec. 4.3, and characterizing strong $\lambda_u$-normalization. However, the two systems will not be described and studied in the same way: by lack of space we choose to discuss $H_{\lambda_u}$ in a more informal and compact way, while reserving more space and discussion to system $S_{\lambda_u}$.

The (syntax directed) rules of the typing system $H_{\lambda_u}$ appear in Fig. 5. Rule $(\Rightarrow_4)$ is to be understood as a logical admissible rule: if union (resp. intersection) is interpreted as the OR (resp. AND) logical connective, then $\exists K \in K \ (I_k \Rightarrow U_k)$ and $(\land K \in K \ I_k)$ implies...
This makes a strong contrast with the derivation in Fig. 6, where different uses of names:

\[ \alpha \] that is now discussed.\n
The name \( \mu \beta \) is not free in \( \alpha \). A similar phenomenon occurs with \( \lambda \)-abstractions, which restore the types of the free occurrences of variables in the body of the functions.

In simply typed \( \lambda \)-calculus [32], the \((\#i)\) rule saves a type \( U \) for the name \( \alpha \), however, in our system, the corresponding name assignment \( \Delta \lor \{ \alpha : U \} \), specified by means of \( \lor \), collects all the types that \( \alpha \) has been assigned during the derivation. Notice that the \((\#e)\) rule is not deterministic since \( \Delta(\alpha)^* \) denotes an arbitrary union type, a choice that is now discussed.

In simply typed \( \lambda \), call-

\[ \text{call-cc} = \lambda y.\mu \alpha . [\alpha ] y (\lambda x . \mu \beta . [\alpha ] x) \] would be typed with \( (a \Rightarrow b) \Rightarrow a \) (Peirce’s Law), so that the fact that \( \alpha \) is used twice in the type derivation would not be explicitly materialized (same comment applies to idempotent intersection/union types). This makes a strong contrast with the derivation in Fig. 6, where \( U_a := (a) \), \( U_b := (b) \), \( U_y := (\lambda U_a \Rightarrow U_b) \Rightarrow U_a \) and \( \Phi_y \triangleright y : U_y \vdash y : U_y \). Indeed, we can distinguish two different uses of names:

1. The name \( \alpha \) is saved twice by a \((\#i)\) rule: once for \( x \) and once for \( y (\lambda x . \mu \beta . [\alpha ] x) \), both times with type \( U_a \). After that, the abstraction \( \mu \alpha . [\alpha ] y (\lambda x . \mu \beta . [\alpha ] x) \) restores the types that were previously stored by \( \alpha \). A similar phenomenon occurs with \( \lambda \)-abstractions, which restore the types of the free occurrences of variables in the body of the functions.

2. The name \( \beta \) is not free in \( [\alpha ] x \), so that a new union type \( U_b \) is introduced to type the abstraction \( \mu \beta . [\alpha ] x \). From a logical point of view this corresponds to a weakening on the right hand side of the sequent. Consequently, \( \lambda \) and \( \mu \)-abstractions are not treated symmetrically: when \( x \) is not free in \( t \), then \( \lambda x . t \) will be typed with \( [\alpha ] \Rightarrow \sigma \) (where \( \sigma \) is the type of \( t \)), and no new intersection type is introduced for the abstracted variable \( x \).
Thus, \( \mu \)-abstractions have two uses: to restore saved types and to create new types, which explains the fact that empty union types are banned. Indeed, if \( \Gamma \vdash t : \mathcal{U} \mid \Delta \), then \( \mathcal{U} \neq \langle \rangle \).

Why union types cannot be empty? Let us suppose that empty union types may be introduced by the \((\#_c)\) rule, at least when \( \alpha \notin \text{fn}(c) \), so that for example \( t = \mu \beta. [\alpha] x \) would be typed with \( \langle \rangle \) (this can be obtained by simply changing \( \Delta(\alpha)^* \) to \( \Delta(\alpha) \) in the \((\#_c)\)-rule). Suppose also an object \( o \) containing 2 occurrences of the subterm \([\gamma]t\), so that \( \gamma \) receives the union type \( \langle \rangle \) twice in the corresponding name assignment. Then, the term \( \mu^2. o \) will be typed with \( \langle \rangle = \langle \rangle \lor \langle \rangle \), which does not reflect the fact that \( \gamma \) is used twice, thus loosing the quantitative flavour of the system (see also a formal argument just after Lem. 9).

We define now the notion of size derivation, which is a natural number representing the amount of information in a tree derivation. For any type derivation \( \Phi, sz(\Phi) \) is inductively defined by the following rules, where we use an abbreviated notation for the premises.

\[
\begin{align*}
\text{sz} & : \frac{x : [\mathcal{U}] \vdash x : \mathcal{U} \mid \emptyset}{(ax)} := 1 \\
\text{sz} & : \frac{\Phi_i \vdash t}{\Gamma \vdash x : \lambda x : t : (\Gamma(x) \Rightarrow \mathcal{U}) \mid \Delta}{(\Rightarrow)} := \text{sz}(\Phi_i) + 1 \\
\text{sz} & : \frac{\Phi_i \vdash t}{\Gamma \vdash [\alpha] t : \# \mid \Delta \lor [\alpha] : \mathcal{U}}{(\#_i)} := \text{sz}(\Phi_i) + ar(\mathcal{U}) \\
\text{sz} & : \frac{\Phi_i \vdash c}{\Gamma \vdash \mu \alpha : c : (\Delta(\alpha)^*) \mid \Delta \lor \Delta}{(\#_c)} := \text{sz}(\Phi_i) + 1 \\
\text{sz} & : \frac{\bigwedge_{k \in K} \Gamma_k \vdash \bigwedge_{k \in K} [\mathcal{U}]_{\mathcal{K} \mid \Delta_k} \Rightarrow \Delta_k}{(\lambda)} := \sum_{k \in K} \text{sz}(\Phi_k) \\
\text{sz} & : \frac{\Phi_i \vdash u}{\Gamma \vdash u : \forall k \in K \forall k : \Delta}{(\Rightarrow_\forall)} := \text{sz}(\Phi_i) + \text{sz}(\Phi_u) + |K|
\end{align*}
\]

System \( \mathcal{H}_{\lambda_\mu} \) behaves as expected, in particular, typing is stable by reduction (Subject Reduction) and anti-reduction (Subject Expansion). Moreover,

**Theorem 7.** Let \( o \in \mathcal{O}_{\lambda_\mu} \). Then \( o \) is \( \mathcal{H}_{\lambda_\mu} \)-typable iff \( o \in \mathcal{H}N(\lambda_\mu) \) iff the head-strategy terminates on \( o \). Moreover, if \( o \) is \( \mathcal{H}_{\lambda_\mu} \)-typable with tree derivation \( \Pi \), then \( sz(\Pi) \) gives an upper bound to the length of the head-reduction strategy starting at \( o \).

We do not provide the proof of this theorem, because it uses special cases of the more general technology that we are going to develop later to deal with strong normalization. Notice that Thm. 7 ensures that the head-strategy is complete for head-normalization in \( \lambda_\mu \).

A last comment of this section concerns the restriction of system \( \mathcal{H}_{\lambda_\mu} \) to the pure \( \lambda \)-calculus: union types, name assignments and rules \((\#_c)\) and \((\#_i)\) are no more necessary, so that every union multiset takes the single form \( \langle \tau \rangle \), which can be simply identified with \( \tau \). Thus, the restricted typing system \( \mathcal{H}_{\lambda_\mu} \) becomes the one in Fig. 2.

### 4.3 System \( S_{\lambda_\mu} \)

This section presents a quantitative typing system characterizing strongly \( \beta \)-normalizing \( \lambda_\mu \)-terms. The (syntax directed) typing rules of the typing system \( S_{\lambda_\mu} \) appear in Fig. 7. As in system \( S' \), the operation \( _{\ast}^\lor \) is used to choose arbitrary types for erasable terms, so that no subterm is untyped, thus ensuring strong \( \lambda_\mu \)-normalization. While the use of \( _{\ast}^\lor \) in the \((\#_c)\)-rule can be seen as a weakening on the right hand-sides of sequents, its use in rule \((\Rightarrow_\forall)\) corresponds to a form of controlled weakening on the left hand-sides. We still consider the definition of size given before, as the choice operator does not play any particular role.

As in system \( \mathcal{H}_{\lambda_\mu} \), a term is typed with a non-empty union type.
Figure 7 System $S_{\lambda\mu}$.

**Lemma 8.** If $\vdash \Gamma \vdash t : \Delta$, then $\mathcal{U} \neq \langle \rangle$.

As well as in the case of $H_{\lambda\mu}$, system $S_{\lambda\mu}$ can be restricted to the pure $\lambda$-calculus. Using the same observations at the end of Sec. 4.2 we obtain the typing system $S'_{\lambda}$ in Fig. 4 that characterizes $\beta$-strong normalization.

A key property of system $S_{\lambda\mu}$ is known as relevance:

**Lemma 9 (Relevance).** If $\Phi \vdash \Gamma \vdash o : \mathcal{A} | \Delta$, then $\text{dom}(\Gamma) = \mathcal{FV}(o)$ and $\text{dom}(\Delta) = \mathcal{FV}(o)$.

Relevance holds thanks to the choice operator $\_^\ast$: indeed, if $\Delta(\alpha)^\ast$ is replaced by $\Delta(\alpha)$ in the ($\#_\ast$)-rule, then the following derivations gives a counter-example to the relevance property, where $\alpha \in \mathcal{FV}(\mu[\alpha]\beta.\gamma|x)$ but $\alpha \notin \text{dom}(\gamma : \langle \alpha \rangle)$.

Indeed, the size of derivations typing commands takes into account the arity of their corresponding type; and this is essential to materialize a decreasing measure for $\mu$-reduction (see Sec. 5). Notice that $sz(\Phi) \geq 1$ holds for any regular derivation $\Phi$, whereas, by definition, the derivation of the empty auxiliary judgment $\vdash t : []$ has size 0.

## 5 Typing Properties

This section shows two fundamental properties of reduction (*i.e.* forward) and anti-reduction (*i.e.* backward) of system $S_{\lambda\mu}$. In Sec. 5.1 we analyse the subject reduction (SR) property, and we prove that reduction preserves typing and decreases the size of type derivations (that is why we call it weighted SR). The proof of this property makes use of two fundamental properties (Lem. 11 and 12) guaranteeing well-typedness of the meta-operations of substitution and replacement. Sec. 5.2 is devoted to subject expansion (SE), which states that non-erasing anti-reduction preserves types. The proof uses the fact that reverse substitution (Lem. 13) and reverse replacement (Lem. 14) preserve types.

We start by stating an interesting property, to be used in our forthcoming lemmas, that allows us to split and merge auxiliary derivations:

**Lemma 10.** Let $\mathcal{I} = \land_{k \in K} \mathcal{I}_k$. Then $\Phi \vdash \Gamma \parallel \vdash t : \mathcal{I} | \Delta$ iff $\exists (\Gamma_k)_{k \in K}, \exists (\Delta_k)_{k \in K}$ s.t. $(\Phi_k \vdash \Gamma_k \parallel \vdash t : \mathcal{I}_k | \Delta_k)_{k \in K}$, $\Gamma = \land_{k \in K} \Gamma_k$ and $\Delta = \lor_{k \in K} \Delta_k$. Moreover, $sz(\Phi) = \Sigma_{k \in K} sz(\Phi_k)$. 
5.1 Forward Properties

We first state the substitution lemma, which guarantees that typing is stable by substitution. The lemma also establishes the size of the derivation tree of a substituted object from the sizes of the derivations trees of its components.

► **Lemma 11 (Substitution).** Let $\Theta_u \triangleright \Gamma_u \vdash u : \Delta_u$. If $\Phi_o \triangleright \Gamma ; x : I \vdash o : A | \Delta$, then there is $\Phi_o(x/u)$ such that:

- $\Phi_o(x/u) \triangleright \Gamma \land \Gamma_u \vdash o(x/u) : A | \Delta \lor \Delta_u$.
- $sz(\Phi_o(x/u)) = sz(\Phi_o) + sz(\Theta_u) - |I|$.

**Proof.** By induction on $\Phi_o$ using Lem. 9 and 10. ▼

Typing is also stable by replacement. Moreover, we can specify the exact size of the derivation tree of the replaced object from the sizes of its components.

► **Lemma 12 (Replacement).** Let $\Theta_u \triangleright \Gamma_u \vdash u : \land_{k \in K} (I_k) | \Delta_u$ where $\alpha \notin \text{fn}(u)$. If $\Phi_o \triangleright \Gamma \vdash o : A | \alpha : (I_k \Rightarrow V_k)_{k \in K}; \Delta$, then there is $\Phi_o(\alpha\#u)$ such that:

- $\Phi_o(\alpha\#u) \triangleright \Gamma \land \Gamma_u \vdash o(\alpha\#u) : A | \alpha : \land_{k \in K} V_k; \Delta \lor \Delta_u$.
- $sz(\Phi_o(\alpha\#u)) = sz(\Phi_o) + sz(\Theta_u)$.

**Proof.** By induction on $\Phi_o$ using Lem. 9 and 10. ▼

Notice that the type of $\alpha$ in the conclusion of the derivation $\Phi_o(\alpha\#u)$ (which is $\land_{k \in K} V_k$) is strictly smaller than that of the conclusion of the derivation $\Phi_o$ (which is $\langle I_k \Rightarrow V_k \rangle_{k \in K}$) if and only if $K \neq \emptyset$. Lemmas 11 and 12 are used in the proof of the following key property.

► **Property 1 (Weighted Subject Reduction for $\lambda u$).** Let $\Phi_o \vdash o : A | \Delta$. If $o \rightarrow o'$ is a non-erasing step, then there exists a derivation $\Phi' \vdash o' : A | \Delta$ such that $sz(\Phi) > sz(\Phi')$.

**Proof.** By induction on $o \rightarrow o'$ using Lem. 9, 11 and 12. ▼

**Discussion.** A first remark about the property above is that variable and name assignments are not necessarily preserved by erasing reductions. Thus for example, consider $t = \langle \lambda y.x \rangle z \rightarrow x = t'$. The term $t$ is typed with a variable assignment whose domain is $\{x, z\}$, while $t'$ can only be typed with an assignment whose domain is $\{x\}$. Concretely, starting from a derivation of $x : [\langle a \rangle], z : [\langle b \rangle] \vdash (\lambda x.y) z : \langle a \rangle$ (the simplified type derivation of this term in the $\mathcal{S}'_k$ system appears on page 6), we can only construct a derivation of $x : [\langle a \rangle], z : [\langle a \rangle]$ so that the type is preserved while the variable assignment is not. Actually, our restricted form of subject reduction (i.e. for non-erasing steps only) is sufficient for our purpose (see how we deal with the erasing steps in the proof of Lem. 16).

A second remark is that the consideration of arities of names in the definition of the size of derivations (third case $(\#_c)$) is crucial to guarantee that $\mu$-reduction decreases $sz(\_)$.

This is perfectly reflected in Lem. 12, where the type of $\alpha$ in the conclusion of the derivation $\Phi_o(\alpha\#u)$ is strictly smaller than that of the conclusion of the derivation $\Phi_o$.

A third point is about the use of the choice operator in the typing rule $(\#_c)$, which does not allow for the type $\langle \_ \rangle$ to be assigned to $\alpha$ when $\alpha \notin \text{fn}(c)$. More precisely, assume, just temporarily, that the $(\#_c)$ rule does not use the choice operator, so that a $\mu$-abstraction can be typed with $\langle \_ \rangle$. Set $u := \mu \beta.\langle \gamma \rangle y$ and $e := [\alpha]\mu \delta.\langle \alpha \rangle u$ so that $u, \mu \beta.\langle \gamma \rangle y$ and $\mu \alpha.c$ are typed with $\langle \_ \rangle$. The resulting type derivation $\Phi_o \triangleright \Gamma \vdash c : \# | \Delta$ contradicts the Relevance Lem. 9, simply because $\alpha \notin \text{fn}(\Delta)$ but $\alpha$ has two free occurrences in $c$. This has heavy consequences that can be illustrated by the reduction sequence $t = (\mu \alpha.c)x \rightarrow \mu \alpha.[\alpha](\mu \delta.\langle \alpha \rangle (\mu \beta.\langle \gamma \rangle y) x) x \rightarrow^{*} \mu \alpha.c = t'$. Indeed, the type of $\mu \alpha.c$, which is $\langle \_ \rangle$, holds no
information capturing the number of free occurrences of $\alpha$ in $c$, so that there is no local way to know how many times the argument $x$ should be typed in the whole derivation of the term $(\mu \alpha. c) x$. This prevents the reduction relation to decrease any reasonable measure associated to type derivations.

### 5.2 Backward Properties

Subject expansion is based on two technical properties: the first one, called reverse substitution, allows us to extract type information for an object $o$ and a term $u$ from the type derivation of $o \{x/u\}$; similarly, the second one, called reverse replacement, gives type information for a command $c$ and a term $u$ from the type derivation of $c \{\alpha//u\}$. Both of them are proved by induction on derivations using Lem. 9 and 10. Formally,

**Lemma 13 (Reverse Substitution).** Let $\Phi \triangleright \Gamma' \vdash o \{x/u\} : A \mid \Delta'$. Then $\exists \Gamma', \exists \Delta, \exists \Gamma_u, \exists \Delta_u$ such that: $\Gamma' = \Gamma \wedge \Gamma_u$, $\Delta' = \Delta \vee \Delta_u$, $\triangleright \Gamma; x : I \vdash o : A \mid \Delta$ and $\triangleright \Gamma_u \vdash u : I \mid \Delta_u$.

**Lemma 14 (Reverse Replacement).** Let $\Phi \triangleright \Gamma' \vdash o \{\alpha//u\} : A \mid \Delta'$, where $\alpha \notin \text{fn}(u)$. Then $\exists \Gamma', \exists \Delta, \exists \Gamma_u, \exists (I_k)_{k \in K}, \exists (\nu_k)_{k \in K}$ such that: $\Gamma' = \Gamma \wedge \Gamma_u$, $\Delta' = \Delta \vee \Delta_u$, $\nu = \nu_k \in K, \nu \triangleright \Gamma \vdash o : A \mid \alpha : (I_k \rightarrow \nu_k)_{k \in K} : \Delta$, and $\triangleright \Gamma_u \vdash u : \lambda k \in K I_k \mid \Delta_u$.

The following property will be used in Sec. 6 to show that normalization implies typability.

**Property 2 (Subject Expansion for $\lambda_\mu$).** Assume $\Phi \triangleright \Gamma' \vdash o' : A \mid \Delta'$. If $o \rightarrow o'$ is a non-erasing step, then there is $\Phi \triangleright \Gamma' \vdash o : A \mid \Delta'$.

**Proof.** By induction on $\rightarrow$ using Lem. 9, 13 and 14.

### 6 Strongly Normalizing $\lambda_\mu$-Objects

In this section we show the characterization of strongly-normalizing terms of the $\lambda_\mu$-calculus by means of the typing system introduced in Sec. 4, i.e. we show that an object $o$ is strongly-normalizing iff $t$ is typable.

The proof of our main result (Thm. 18) relies on the following two ingredients:

1. Every $S_{\lambda_\mu}$-typable object is in $SN(\lambda_\mu)$ (Lem. 16).
2. Every object in $SN(\lambda_\mu)$ is $S_{\lambda_\mu}$-typable (Lem. 17).

First, we inductively reformulate the set of strongly normalizing objects: the set $I(\lambda_\mu)$ is defined as the smallest subset of $O_{\lambda_\mu}$ satisfying the following closure properties:

1. If $t_1, \ldots, t_n (n \geq 0) \in I(\lambda_\mu)$, then $x t_1 \ldots t_n \in I(\lambda_\mu)$.
2. If $t \in I(\lambda_\mu)$, then $\lambda x.t \in I(\lambda_\mu)$.
3. If $c \in I(\lambda_\mu)$, then $\mu \alpha.c \in I(\lambda_\mu)$.
4. If $t \in I(\lambda_\mu)$, then $[\alpha] t \in I(\lambda_\mu)$.
5. If $u, t\{x//u\} \bar{\sigma} (n \geq 0) \in I(\lambda_\mu)$, then $[\lambda x.t] u \bar{\sigma} \in I(\lambda_\mu)$.
6. If $u, (\mu \alpha.c \{\alpha//u\}) \bar{\sigma} (n \geq 0) \in I(\lambda_\mu)$, then $(\mu \alpha.c) u \bar{\sigma} \in I(\lambda_\mu)$.

The sets $SN(\lambda_\mu)$ and $I(\lambda_\mu)$ turn out to be equal, as expected:

**Lemma 15.** $SN(\lambda_\mu) = I(\lambda_\mu)$.

**Proof.** $SN(\lambda_\mu) \subseteq I(\lambda_\mu)$ is proved by induction on the pair $\langle \eta(o), |o| \rangle$ endowed with the lexicographic order, where $\eta(o)$ denotes the maximal length of an $\lambda_\mu$-reduction sequence starting at $o$ and $|o|$ denotes the size of $o$. $I(\lambda_\mu) \subseteq SN(\lambda_\mu)$ is proved by induction on $I(\lambda_\mu)$ using Cor. 1. No reducibility argument is then needed in this proof.
Lemma 16. If $o$ is $S_{\lambda_{\mu}}$-typable, then $o \in SN(\lambda_{\mu})$.

Proof. We proceed by induction on $sz(\Phi)$, where $\Phi \vdash \Gamma \vdash o : A | \Delta$. When $\Phi$ does not end with the rule ($\Rightarrow$) the proof is straightforward, so we consider $\Phi$ ends with ($\Rightarrow$), where $A = U$ and $o = x_{t_1} \ldots t_n$ or $o = (\mu_{\alpha}.c)t_1 \ldots t_n$ or $o = (\lambda_{\alpha}.u)t_1 \ldots t_n$, where $n \geq 1$.

By construction there are subderivations $(\Phi_{t_i})_{i \in \{1 \ldots n\}}$ such that $(sz(\Phi_{t_i}))_{i \in \{1 \ldots n\}}$ is typable in system $H_{\alpha}$. Moreover, we reason similarly to the previous one.

Lemma 17. If $o \in SN(\lambda_{\mu})$, then $o$ is $S_{\lambda_{\mu}}$-typable.

Proof. Thanks to Lem. 15 we can reason by induction on $o \in I(\lambda_{\mu}) = SN(\lambda_{\mu})$. The four first cases are straightforward.

Lem. 16 and 17 allow us to conclude with the main result of this paper which is the equivalence between typability and strong-normalization for the $\lambda_{\mu}$-calculus. Notice that no reducibility argument was used in the whole proof.

Theorem 18. Let $o \in O_{\lambda_{\mu}}$. Then $o$ is typable in system $S_{\lambda_{\mu}}$ iff $o \in SN(\lambda_{\mu})$. Moreover, if $o$ is $S_{\lambda_{\mu}}$-typable with tree derivation $\Pi$, then $sz(\Pi)$ gives an upper bound to the maximal length of a reduction sequence starting at $o$.

To prove the second statement it is sufficient to endow the system with non-relevant axioms for variables and names. This modification, which does not recover subject expansion, is however sufficient to guarantee weighted subject reduction in all the cases (erasing and non-erasing steps) without changing the original measure of the derivations in system $S_{\lambda_{\mu}}$.

7 Conclusion

This paper provides two quantitative type assignment systems $H_{\lambda_{\mu}}$ and $S_{\lambda_{\mu}}$ for $\lambda_{\mu}$, characterizing, respectively, head and strongly normalizing terms. We have shown that whenever $o$ is typable in system $H_{\lambda_{\mu}}$, then we can extract a measure from its type derivation which provides an upper bounds to the length of the head-reduction strategy starting at $o$. The
same happens with system $S_{\lambda\mu}$ with respect to the maximal length of a reduction sequence starting at $o$: indeed, the system $S_{\lambda\mu}$ endowed with weakening axioms enjoys full subject reduction (on erasing and non-erasing steps), and $S_{\lambda\mu}$ can be embedded in such a system by preserving the size of derivations.

The construction of these typing systems suggests the definition of a resource aware calculus, coming along with the corresponding extensions of the typing systems presented here, and implementing a small step operational semantics for classical natural deduction. Unfortunately we cannot provide here the details of such development due to lack of space, but they can be found in [26]. Such a calculus can be seen as an extension of the substitution at a distance paradigm [2, 1] to the classical case.

Quantitative types are a powerful tool to provide relational models for $\lambda$-calculus [14, 3]. The construction of such models for $\lambda\mu$ should be investigated, particularly to understand in the classical case the collapse relation between quantitative and qualitative models [18].

We expect to be able to transfer the ideas in this paper to a classical sequent calculus system, as was already done for focused intuitionistic logic [25].

The fact that idempotent types were already used to show observationally equivalence between call-by-name and call-by-need [23] in intuitionistic logic suggests that our typing system $S_{\lambda\mu\tau}$ could be used in the future to understand from a semantical point of view the fact that classical call-by-name and classical call-by-need are not observationally equivalent [33]. Moreover, it is possible to obtain exact bounds (as in [5]) for the lengths of the head-reduction and the perpetual reduction sequences. For that, it is necessary to integrate some additional typing rules being able to type the constructors appearing in the normal forms of the terms. Although this concrete development remains as future work, the difficult and conceptual part of the technique stays in finding the decreasing measure for reduction, which is one of the contributions of this paper.

The inhabitation problem for $\lambda$-calculus is known to be undecidable for idempotent intersection types [35], but decidable for the non-idempotent ones [7]. We may conjecture that inhabitation is also decidable for $H_{\lambda\mu\tau}$.

Acknowledgment: We would like to thank Vincent Guisse, who started a reflexion on quantitative types for the $\lambda\mu$-calculus during his M1 stage in Univ. Paris-Diderot.
