Realizability algebras III: some examples

Jean-Louis Krivine

Introduction

The notion of realizability algebra, which was introduced in [17, 18], is a tool to study the proof-program correspondence and to build new models of set theory, which we call realizability models of ZF.

It is a variant of the well known notion of combinatory algebra, with a new instruction $cc$, and a new type for the environments.

The sets of forcing conditions, in common use in set theory, are (very) particular cases of realizability algebras; and the forcing models of ZF are very particular cases of realizability models.

We show here how to extend an arbitrary realizability algebra, by means of a certain set of conditions, so that the axiom DC of dependent choice is realized.

In order to avoid introducing new instructions, we use an idea of A. Miquel [19].

This technique has applications of two kinds:

1. Construction of models of ZF + DC.

When the initial realizability algebra is not trivial (that is, if we are not in the case of forcing or equivalently, if the associated Boolean algebra $\mathbb{I}$ is $\neq \{0, 1\}$), then we always obtain in this way a model of ZF which satisfies $DC +$ there is no well ordering of $\mathbb{R}$.

By suitably choosing the realizability algebras, we can get, for instance, the relative consistency over ZF of the following two theories:

i) $ZF + DC +$ there exists an increasing function $i \mapsto X_i$, from the countable atomless Boolean algebra $\mathcal{B}$ into $\mathcal{P}(\mathbb{R})$ such that:

$X_0 = \{0\}; i \neq 0 \Rightarrow X_i$ is uncountable;

$X_i \cap X_j = X_{i \wedge j}$;

if $i \wedge j = 0$ then $X_{i \vee j}$ is equipotent with $X_i \times X_j$;

$X_i \times X_j$ is equipotent with $X_i$;

there exists a surjection from $X_1$ onto $\mathbb{R}$;

if there exists a surjection from $X_j$ onto $X_i$, then $i \leq j$;

if $i, j \neq 0, i \wedge j = 0$, there is no surjection from $X_i \uplus X_j$ (disjoint union) onto $X_i \times X_j$;

more generally, if $A \subset \mathcal{B}$ and if there exists a surjection from $\bigcup_{j \in A} X_j$ onto $X_i$, then $i \leq j$ for some $j \in A$. 

1
In particular, there exists a sequence of subsets of \( \mathbb{R} \), the cardinals of which are not comparable, and also a sequence of subsets of \( \mathbb{R} \), the cardinals of which are strictly decreasing.

ii) ZF + DC + there exists \( X \subset \mathbb{R} \) such that:
- \( X \) is uncountable and there is no surjection from \( X \) onto \( \aleph_1 \) (and therefore, every well orderable subset of \( X \) is countable);
- \( X \times X \) is equipotent with \( X \);
- there exists a total order on \( X \), every proper initial segment of which is countable;
- there exists a surjection from \( X \times \aleph_1 \) onto \( \mathbb{R} \);
- there exists an injection from \( \aleph_1 \) (thus also from \( X \times \aleph_1 \)) into \( \mathbb{R} \).

2. Curry-Howard correspondence.

With this technique of extension of realizability algebras, we can obtain a program from any proof, in ZF + DC, of an arithmetical formula \( F \), which is a \( \lambda_c \)-term, that is, a \( \lambda \)-term containing \( cc \), but no other new instruction.

This is a notable difference with the method given in [14, 15], where we use the instruction quote and which is, on the other hand, simpler and not limited to arithmetical formulas.

It is important to observe that the program we get in this way does not really depend on the given proof of \( DC \rightarrow F \) in ZF, but only on the program \( P \) extracted from this proof, which is a closed \( \lambda_c \)-term. Indeed, we obtain this program by means of an operation of compilation applied to \( P \) (look at the remark at the end of the introduction of [17]).

Finally, apart from applications 1 and 2, we may notice theorem 27, which gives an interesting property of every realizability model: as soon as the Boolean algebra \( \mathcal{I} \) is not trivial (i.e. if the model is not a forcing model), there exists a non well orderable individual.

Acknowledgements. I want to thank the referees, especially the second one for numerous pertinent and helpful remarks and suggestions.

1 Generalities

1.1 Realizability algebras

It is a first order structure, which is defined in [17]. We recall here briefly the definition (with a little change) and some essential properties:

A realizability algebra \( \mathcal{A} \) is made up of three sets: \( \Lambda \) (the set of terms), \( \Pi \) (the set of stacks), \( \Lambda \star \Pi \) (the set of processes) with the following operations:

\[ (\xi, \eta) \mapsto (\xi) \eta \text{ from } \Lambda^2 \text{ into } \Lambda \text{ (application)}; \]
\[ (\xi, \pi) \mapsto \xi \star \pi \text{ from } \Lambda \times \Pi \text{ into } \Pi \text{ (push)}; \]
\[ (\xi, \pi) \mapsto \xi \star \pi \text{ from } \Lambda \times \Pi \text{ into } \Lambda \star \Pi \text{ (process)}; \]
\[ \pi \mapsto k_\pi \text{ from } \Pi \text{ into } \Lambda \text{ (continuation)}. \]

There are, in \( \Lambda \), distinguished elements \( B, C, I, K, W, cc \), called elementary combinators or instructions.

Notation. The term \( (\ldots ((\xi) \eta_1) \eta_2) \ldots ) \eta_n \) will be also written as \( (\xi) \eta_1 \eta_2 \ldots \eta_n \) or \( \xi \eta_1 \eta_2 \ldots \eta_n \).

For instance: \( \xi \eta \zeta = (\xi) \eta \zeta = (\xi \eta) \zeta = ((\xi) \eta) \zeta \).
We define a preorder on $\Lambda \star \Pi$, denoted by $>$, which is called execution; $\xi \star \pi > \xi' \star \pi'$ is read as: the process $\xi \star \pi$ reduces to $\xi' \star \pi'$.

It is the smallest reflexive and transitive binary relation, such that, for any $\xi, \eta, \zeta \in \Lambda$ and $\pi, \delta \in \Pi$, we have:

$$(\xi) \eta \star \pi > \xi \star \eta \star \pi.$$  

$L \star \xi \cdot \eta \star \pi > \xi \star \pi.$

$K \star \xi \cdot \eta \star \pi > \xi \star \pi.$

$W \star \xi \cdot \eta \star \pi > \xi \star \eta \star \pi.$

$C \star \xi \cdot \eta \star \zeta \star \pi > \xi \star \zeta \star \eta \star \pi.$

$B \star \xi \cdot \eta \star \zeta \star \pi > \xi \cdot (\eta) \zeta \star \pi.$

$C \star \xi \cdot \pi > \xi \star k \star \pi.$

$k \star \xi \cdot \pi > \xi \star \pi.$

We are also given a subset $\bot$ of $\Lambda \star \Pi$ such that:

$$\xi \star \pi > \xi' \star \pi', \xi \star \pi' \in \bot \Rightarrow \xi \star \pi \in \bot.$$  

Given two processes $\xi \star \pi, \xi' \star \pi'$, the notation $\xi \star \pi \Rightarrow \xi' \star \pi'$ means:

$$\xi \star \pi \notin \bot \Rightarrow \xi' \star \pi' \notin \bot.$$  

Therefore, obviously, $\xi \star \pi > \xi' \star \pi' \Rightarrow \xi \star \pi \Rightarrow \xi' \star \pi'.$

Finally, we choose a set of terms $QP_{dfr} \subset \Lambda$, containing the elementary combinators: $B, C, I, K, W, cc$ and closed by application. They are called the proof-like terms of the algebra $A$. We write also $QP$ instead of $QP_{dfr}$ if there is no ambiguity about $A$.

The algebra $A$ is called coherent if, for every proof-like term $\theta \in QP_{dfr}$, there exists a stack $\pi$ such that $\theta \star \pi \notin \bot$.

**Remark.** The sets of forcing conditions can be considered as degenerate cases of realizability algebras, if we present them in the following way: an inf-semi-lattice $P$, with a greatest element $I$ and an initial segment $\bot$ of $P$ (the set of false conditions). Two conditions $p, q \in P$ are called compatible if their g.l.b. $p \land q$ is not in $\bot$.

We get a realizability algebra if we set $\Lambda = \Pi = \Lambda \star \Pi = P$; $B = C = I = K = W = cc = I$ and $QP = \{ I \}$; $(p) q = p \star q = p \star q = p \land q$ and $k_p = p$. The preorder $p > q$ is defined as $p \leq q$, i.e. $p \land q = p$. The condition of coherence is $I \notin \bot$.

### 1.2 c-terms and $\lambda$-terms

The terms of the language of combinatory algebra, which are built with variables, the constant symbols $B, C, I, K, W, cc$ and the application (binary operation), will be called combinatory terms or c-terms, in order to distinguish them from the terms of the algebra $A$, which are elements of $\Lambda$.

Each closed c-term (i.e. without variable) takes a value in the algebra $A$, which is a proof-like term of $A$.

Let us call atom a c-term of length 1, i.e. a constant symbol $B, C, I, K, W, cc$ or a variable.

**Lemma 1.** Every c-term $t$ can be written, in a unique way, in the form $t = (a) t_1 \ldots t_k$ where $a$ is an atom and $t_1, \ldots, t_k$ are c-terms.
Lemma 4.
Let $a$ be an atom, $t$ a $c$-term (i.e. an element of $\Lambda$) denoted by $t[\xi_1/x_1, \ldots, \xi_n/x_n]$ or, more briefly, $t[\xi/x]$.

The inductive definition is:

- $a[\xi/x] = \xi$ if $a = x_i (1 \leq i \leq n)$;
- $\lambda a[\xi/x] = a$ if $a$ is an atom,
- $(tu)[\xi/x] = (t[\xi/x])(u[\xi/x])$.

Given a $c$-term $t$ and a variable $x$, we define inductively on $t$, a new $c$-term denoted by $\lambda x t$, which does not contain $x$. To this aim, we apply the first possible case in the following list:

1. $\lambda x t = (K)t$ if $t$ does not contain $x$.
2. $\lambda x x = I$.
3. $\lambda x(t)u = (C\lambda x t)u$ if $u$ does not contain $x$.
4. $\lambda x(t)x = t$ if $t$ does not contain $x$.
5. $\lambda x(t)x = (W)\lambda x t$ (if $t$ contains $x$).
6. $\lambda x(t)(u)v = \lambda x((B)t)u v$ (if $uv$ contains $x$).

**Lemma 2.** This rewriting is finite for every $c$-term.

For each $c$-term $t$, we define inductively as follows the integers $l[t], v_0[t], v_1[t], v_2[t]$: $l[a] = 1$ for every atom $a$; $l((t)u) = l[t] + l[u] + 2$; $v_0[a] = 0$ for every atom $a$; $v_0[(t)u] = l[u]$; $v_1[x] = 1$; $v_1[a] = 0$ for every atom $a \neq x$; $v_1[(t)u] = v_1[t] + v_1[u]$; $v_2[t] = 0$ if $x$ is not in $t$; $v_2[x] = 1$; $v_2[(t)u] = v_2[u]$ if $x$ appears in $u$; $v_2[(t)u] = v_2[t] + l[u] + 1$ if $x$ is not in $u$ (and then $x$ appears in $t$).

$l[t]$ is the length of $t$;
$v_0[t]$ is the length of the argument, when $t$ is an application;
$v_1[t]$ is the number of occurrences of $x$ in $t$;
$v_2[t]$ is the distance to the end of the term $t$, of the last occurrence of $x$ in $t$.

Rule 5 strictly decreases $v_1(t)$; rule 3 does not change $v_1[t]$ and strictly decreases $v_2[t]$; rule 6 does not change $v_1[t]$ and $v_2[t]$ and strictly decreases $v_0[t]$.

Therefore, after a finite number of applications of rules 3, 5 and 6, we must apply one of the rules 1, 2 or 4, and the rewriting stops.

Q.E.D.

Given a $c$-term $t$ and a variable $x$, we now define the $c$-term $\lambda x t$ by setting:

$\lambda x t = \lambda x (l)t$.

This enables us to translate every $\lambda$-term into a $c$-term. In the sequel, almost all $c$-terms will be written as $\lambda$-terms.

The fundamental property of this translation is given by theorem 3:

**Theorem 3.** Let $t$ be a $c$-term with the only variables $x_1, \ldots, x_n$; let $\xi_1, \ldots, \xi_n \in \Lambda$ and $\pi \in \Pi$. Then $\lambda x_1 \ldots \lambda x_n t \star \xi_1 \cdots \star \xi_n \star \pi > t[\xi_1/x_1, \ldots, \xi_n/x_n] \star \pi$.

**Lemma 4.** Let $a$ be an atom, $t = (a)t_1 \ldots t_k$ a $c$-term with the only variables $x, y_1, \ldots, y_n$, and $\xi, \eta_1, \ldots, \eta_n \in \Lambda$; then $(\lambda x t)[\eta/\bar{y}] \star \xi \star \pi > a[\xi/x, \eta/\bar{y}] \star t_1[\xi/x, \eta/\bar{y}] \cdots \star t_k[\xi/x, \eta/\bar{y}] \star \pi$. 

4
The proof is done by induction on the number of rules 1 to 6 used to translate the term $\lambda x \, t$. Consider the rule used first.

• Rule 1: we have $(\lambda x \, t)[\eta/\bar{y}] \cdot \xi \cdot \pi \equiv (K) \, t[\eta/\bar{y}] \cdot \xi \cdot \pi > K \cdot t[\eta/\bar{y}] \cdot \xi \cdot \pi > t[\eta/\bar{y}] \cdot \pi$

• Rule 2: we have $t = x$, $\forall x \, t = 1$ and the result is trivial.

In rules 3, 4, 5 or 6, we have $t = u t_k$ with $u = a t_1 \ldots t_{k-1}$, by lemma 1.

- Rule 3: $(\lambda x \, t)[\eta/\bar{y}] \cdot \xi \cdot \pi \equiv ((C \lambda x \, u) t_k)[\eta/\bar{y}] \cdot \xi \cdot \pi > C \cdot ((\lambda x \, u)[\eta/\bar{y}] \cdot t_k[\eta/\bar{y}] \cdot \xi \cdot \pi$

- Rule 4: we have $(\lambda x \, t)[\eta/\bar{y}] \cdot \xi \cdot \pi \equiv u[\eta/\bar{y}] \cdot \xi \cdot \pi > u[\xi/x, \eta/\bar{y}] \cdot \xi \cdot \pi$ because $x$ is not in $u$.

- Rule 5: we have $t_k = x$ and $(\lambda x \, t)[\eta/\bar{y}] \cdot \xi \cdot \pi \equiv (W \lambda x \, u)[\eta/\bar{y}] \cdot \xi \cdot \pi$

- Rule 6: we have $t_k = (u \, w) \cdot (\lambda x \, t)[\eta/\bar{y}] \cdot \xi \cdot \pi \equiv (\lambda x \, (B) \, u \cdot v \cdot w)[\eta/\bar{y}] \cdot \xi \cdot \pi$

The result follows immediately.

Q.E.D.

Lemma 5. $(\lambda x \, t)[\eta/\bar{y}] \cdot \xi \cdot \pi > t[\xi/x, \eta/\bar{y}] \cdot \pi$.

Immediate by lemma 4 and the definition of $\lambda x \, t$ which is $\lambda x \, (l) \, t$.

Q.E.D.

We can now prove theorem 3 by induction on $n$; the case $n = 0$ is trivial.

We have $\lambda x_1 \ldots \lambda x_n \lambda x \, t \cdot \xi_1 \ldots \xi_{n-1} \cdot \xi_n \cdot \pi > (\lambda x \, t)[\xi_1/x_1, \ldots, \xi_{n-1}/x_{n-1}] \cdot \xi_n \cdot \pi$

(by induction hypothesis) $t[\xi_1/x_1, \ldots, \xi_{n-1}/x_{n-1}, \xi_n/x_n] \cdot \pi$ by lemma 5.

Q.E.D.

1.3 The formal system

We write formulas and proofs in the language of first order logic. This formal language consists of:

- individual variables $x, y, \ldots$;
- function symbols $f, g, \ldots$ of various arities; function symbols of arity 0 are called constant symbols.
- relation symbols; there are three binary relation symbols: $\equiv$, $\in$, $\subset$.

The terms of this first order language will be called $\ell$-terms; they are built in the usual way with individual variables and function symbols.

Remark. Thus, we use four expressions with the word term: term, c-term, $\lambda$-term and $\ell$-term.
The **atomic formulas** are the expressions $\top, \bot, t \not\in u, t \subseteq u$, where $t, u$ are $\ell$-terms.

**Formulas** are built as usual, from atomic formulas, with the only logical symbols $\rightarrow, \forall$:

- each atomic formula is a formula;
- if $A, B$ are formulas, then $A \rightarrow B$ is a formula;
- if $A$ is a formula and $x$ an individual variable, then $\forall x A$ is a formula.

**Notations.** Let $A_1, \ldots, A_n, A, B$ be formulas. Then:

1. $x_1 : A_1, \ldots, x_n : A_n \vdash x_i : A_i$.
2. $x_1 : A_1, \ldots, x_n : A_n \vdash t : A \rightarrow B, \ x_1 : A_1, \ldots, x_n : A_n \vdash u : A \Rightarrow x_1 : A_1, \ldots, x_n : A_n \vdash tu : B$.
3. $x_1 : A_1, \ldots, x_n : A_n, x : A \vdash t : A \Rightarrow x_1 : A_1, \ldots, x_n : A_n \vdash \lambda x t : A \rightarrow B$.
4. $x_1 : A_1, \ldots, x_n : A_n \vdash t : A \Rightarrow x_1 : A_1, \ldots, x_n : A_n \vdash t : \forall x A$ where $x$ is an individual variable which does not appear in $A_1, \ldots, A_n$.
5. $x_1 : A_1, \ldots, x_n : A_n \vdash t : \forall x A \Rightarrow x_1 : A_1, \ldots, x_n : A_n \vdash t : A[\tau/x]$ where $x$ is an individual variable and $\tau$ is a $\ell$-term.
6. $x_1 : A_1, \ldots, x_n : A_n \vdash cc : ((A \rightarrow B) \rightarrow A)$ (law of Peirce).
7. $x_1 : A_1, \ldots, x_n : A_n \vdash t : \bot \Rightarrow x_1 : A_1, \ldots, x_n : A_n \vdash t : A$ for every formula $A$.

### 1.4 Realizability models

We formalize set theory with the first order language described above. We write, in this language, the axioms of a theory named $ZF_e$, which are given in [18].

The usual set theory $ZF$ is supposed written with the only relation symbols $\in, \subset$.

Then, $ZF_e$ is a conservative extension of $ZF$, which is proved in [18].

**Remark.** In $ZF_e$, we have two membership relations $:\in$ which the weak or extensional one, and $\epsilon$ which is the strong one and does not satisfy extensionality.

Therefore, we have also two relations of inclusion $: x \subseteq y \equiv \forall z (z \in y \rightarrow z \not\in x)$ (\$c$-inclusion or $ZF$-inclusion) and $x \subseteq y \equiv \forall z (z \not\in y \rightarrow z \not\in x)$ ($\epsilon$-inclusion). Finally, we have three notions of equality:

- the weakest one is $x \sim y$ $\equiv x \subseteq y \land y \subseteq x$ ($\epsilon$-equality);
- the strongest one is $x = y$ $\equiv \forall z (x \not\in z \rightarrow y \not\in z)$ (Leibniz equality);
- the middle one is $x = y$ $\equiv x \subseteq y \land y \subseteq x$ ($\epsilon$-equality).

Let us consider a coherent realizability algebra $\mathcal{A}$, defined in a model $\mathcal{M}$ of $ZF + V = L$, which is called the ground model. The elements of $\mathcal{M}$ will be called individuals (in order to avoid the word set, as far as possible).

We defined, in [18], a realizability model, denoted by $\mathcal{N}_{\mathcal{A}}$ (or even $\mathcal{N}$, if there is no ambiguity about the algebra $\mathcal{A}$).

It has the same domain (the same individuals) as $\mathcal{M}$ and the interpretation of the function symbols is the same as in $\mathcal{M}$.

Each closed formula $F$ of $ZF_e$ with parameters in $\mathcal{M}$, has two truth values in $\mathcal{N}$, which are
denoted by $\| F \|$ (which is a subset of $\Pi$) and $|F|$ (which is a subset of $\Lambda$).

Here are their definitions:

$|F|$ is defined immediately from $\| F \|$ as follows:

$$\xi \in |F| \Leftrightarrow (\forall \pi \in \| F \|) \xi * \pi \in \bot.$$ 

We shall write $\xi \vdash F$ (read “$\xi$ realizes $F$”) for $\xi \in |F|$.

$\| F \|$ is now defined by recurrence on the length of $F$:

- $F$ is atomic;
  - then $F$ has one of the forms $\top, \bot, a \neq b, a \subset b, a \not\in b$ where $a, b$ are parameters in $\mathcal{M}$. We set:
    $$\| \top \| = \emptyset; \quad \| \bot \| = \Pi; \quad \| a \neq b \| = \{ \pi \in \Pi; (a, \pi) \in b \}.$$ 
    $$\| a \subset b \|, \| a \not\in b \|$$ are defined simultaneously by induction on $(\text{rk}(a) \cup \text{rk}(b), \text{rk}(a) \cap \text{rk}(b))$ ($\text{rk}(a)$ being the rank of $a$ in $\mathcal{M}$).

- $\| a \subset b \| = \bigcup_c [\xi * \pi; \xi \in \Lambda, \pi \in \Pi, (c, \pi) \in a, \xi \vdash c \not\in b]$;
- $\| a \not\in b \| = \bigcup_c [\xi * \pi * \xi'; \xi, \xi' \in \Lambda, \pi \in \Pi, (c, \pi) \in b, \xi \vdash a \subset c, \xi' \vdash c \subset a]$.

- $F \equiv A \rightarrow B$; then $\| F \| = [\xi * \pi; \xi \equiv A, \pi \in \| B \|]$.
- $F \equiv \forall x A$; then $\| F \| = \bigcup_a \| A[a/x] \|$.

The following theorem, proved in [18], is an essential tool:

**Theorem 6 (Adequacy lemma).**

Let $A_1, \ldots, A_n, A$ be closed formulas of $\text{ZF}_e$, and suppose that $x_1 : A_1, \ldots, x_n : A_n \vdash t : A$. If $\xi_1 \vdash A_1, \ldots, \xi_n \vdash A_n$ then $t[\xi_1/x_1, \ldots, \xi_n/x_n] \vdash A$. In particular, if $t \vdash A$, then $t \vdash A$.

Let $F$ be a closed formula of $\text{ZF}_e$, with parameters in $\mathcal{M}$. We say that $\mathcal{N}_{df}$ realizes $F$ or that $F$ is realized in $\mathcal{N}_{df}$ (which is written $\mathcal{N}_{df} \vdash F$ or even $\vdash F$), if there exists a proof-like term $\theta$ such that $\theta \vdash F$.

It is shown in [18] that all the axioms of $\text{ZF}_e$ are realized in $\mathcal{N}_{df}$, and thus also all the axioms of $\text{ZF}$.

**Remarks.** $\mathcal{N}_{df}$ is not a Tarski model of $\text{ZF}_e$, because the truth values of formulas are not 0 or 1 but subsets of $\Pi$. We can obtain Tarski models by using the completeness theorem, or else an ultrafilter on the set of truth values equipped with a suitable structure of Boolean algebra (see [18]). Note that, doing this, we introduce new individuals in the model, i.e. individuals which are not in $\mathcal{M}$.

An individual $a$ of $\mathcal{M}$ is, in general, not related with its interpretation in $\mathcal{N}_{df}$. For instance, if no element of $a$ is an ordered pair $(b, \pi)$ with $\pi \in \Pi$, then $a$ is interpreted as $\emptyset$ in $\mathcal{N}_{df}$.

Indeed, we have $\| \forall x(a \neq a) \| = \emptyset = \| \top \|$.

**Definitions.** Given a set of terms $X \subset \Lambda$ and a formula $F$, we shall use the notation $X \rightarrow F$ as an extended formula; its truth value is $\| X \rightarrow F \| = [\xi * \pi; \xi \in X, \pi \in \| F \|]$.

Two formulas $F[x_1, \ldots, x_n]$ and $G[x_1, \ldots, x_n]$ of $\text{ZF}_e$ will be called interchangeable if the formula $\forall x_1 \ldots \forall x_n (F[x_1, \ldots, x_n] \leftrightarrow G[x_1, \ldots, x_n])$ is realized.

That is, for instance, the case if $\| F[a_1, \ldots, a_n] \| = \| G[a_1, \ldots, a_n] \|$ or also if $\| F[a_1, \ldots, a_n] \| = \| \neg G[a_1, \ldots, a_n] \|$ for every $a_1, \ldots, a_n \in \mathcal{M}$.

The following lemma gives a useful example:
Lemma 7. For every formula $A$, define $\neg A \in \Lambda$ by $\neg A = \{k_\pi : \pi \in \|A\|\}$.
Then $\neg A \to B$ and $\neg A \to B$ are interchangeable, for every formula $B$.

We have immediately $k_\pi \models \neg A$ for every $\pi \in \|A\|$. Therefore, $\|\neg A \to B\| \subset \|\neg A \to B\|$ and it follows that $\models (\neg A \to B) \to (\neg A \to B)$.

Conversely, let $\xi, \eta \in \Lambda$, $\xi \models \neg A \to B$, $\eta \models \neg B$ and let $\pi \in \|A\|$. We have $\xi k_\pi \models \neg A$, thus $(\eta)(\xi)k_\pi \models \bot$ and therefore $(\eta)(\xi)k_\pi \ast \pi \in \bot$.

It follows that $\theta \ast \xi \ast \eta \ast \pi \in \bot$ with $\theta = \lambda x \lambda y (cc) \lambda k(y)(x) k$.

Finally, we have shown that $\models (\neg A \to B) \to (\neg B \to A)$, from which the result follows.

Q.E.D.

1.5 Equality and type-like sets

The formula $x = y$ is, by definition, $\forall z (x \delta z \to y \delta z)$ (Leibniz equality).

If $t, u$ are $\ell$-terms and $F$ is a formula of $\mathcal{M}$, with parameters in $\mathcal{M}$, we define the formula $t = u \to F$. When it is closed, its truth value is:

$$\|t = u \to F\| = \|\top\| = \emptyset$$ if $\mathcal{M} \models t \neq u$; $\|t = u \to F\| = \|F\|$ if $\mathcal{M} \models t = u$.

The formula $t = u \to \bot$ is written $t \neq u$.

The formula $t_1 = u_1 \to (t_2 = u_2 \to \cdots \to (t_n = u_n \to F)\cdots)$ is written:

$$t_1 = u_1, t_2 = u_2, \ldots, t_n = u_n \to F.$$ The formulas $t = u \to F$ and $t = u \to F$ are interchangeable, as is shown in the:

Lemma 8.

i) $\mathcal{M} \models \forall x \forall y \{ (x = y \to F) \to (x = y \to F) \}$;

ii) $\mathcal{M} \models \forall x \forall y \{ (x = y \to F) \to (x = y \to F) \}$.

i) Trivial.

ii) Let $a, b$ be individuals; let $\xi \models a = b \to F$, $\eta \models a = b$ and $\pi \in \|F\|$. We show that $\eta \ast \xi \ast \pi \in \bot$.

Let $c = \{(b, \pi)\}$; by hypothesis on $\eta$, we have $\eta \models a \delta c \to b \delta c$. Since $\pi \in \|b \delta c\|$, it suffices to show that $\xi \models a \delta c$. This is clear if $a \neq b$, since $\|a \delta c\| = \emptyset$ in this case.

If $a = b$, then $\xi \models F$, by hypothesis on $\xi$, thus $\xi \ast \pi \in \bot$; but $\|a \delta c\| = \{\pi\}$ in this case, and therefore $\xi \models a \delta c$.

Q.E.D.

We set $\exists X = X \times \Pi$ for every individual $X$ of $\mathcal{M}$; we define the quantifier $\forall x \exists X$ as follows:

$$\|\forall x \exists X F[x]\| = \bigcup_{a \in X} \|F[a]\|.$$ Of course, we set $\exists x \exists X F[x] \equiv \neg \forall x \exists X \neg F[x]$.

The quantifier $\forall x \exists X$ has the intended meaning, which is that the formulas $\forall x \exists X F[x]$ and $\forall x (x \epsilon X \to F[x])$ are interchangeable. This is shown by the:

Lemma 9.

$\mathcal{M} \models \forall x \exists X F[x] \to \forall x \exists X \neg \neg F[x]$;

$\mathcal{C} \models \forall x \exists X \neg \neg F[x] \to \forall x \exists X F[x]$;

$$\|\forall x \exists X \neg \neg F[x]\| = \|\forall x (\neg F[x] \to x \epsilon \exists X)\|.$$ Immediate.

Q.E.D.
Each functional \( f : \mathcal{M}^n \to \mathcal{M} \), defined in \( \mathcal{M} \) by a formula of ZF with parameters, gives a function symbol, that we denote also by \( f \), and which has the same interpretation in the realizability model \( \mathcal{N}_{af} \).

**Proposition 10.**

Let \( t, t_1, \ldots, t_n, u, u_1, \ldots, u_n \) be \( \ell \)-terms, built with variables \( x_1, \ldots, x_k \) and function symbols of \( \mathcal{M} \).

i) If \( \mathcal{M} \models \forall x_1 \ldots \forall x_k(t_1 = u_1, \ldots, t_k = u_k \rightarrow t = u) \), then :

\[ l \models \forall x_1 \ldots \forall x_k(t_1 = u_1, \ldots, t_k = u_k \leftarrow t = u). \]

ii) If \( \mathcal{M} \models (\forall x_1 \in X_1) \ldots (\forall x_k \in X_k)(t_1 = u_1, \ldots, t_k = u_k \rightarrow t = u) \), then :

\[ l \models (\forall x_1 \in X_1) \ldots (\forall x_k \in X_k)(t_1 = u_1, \ldots, t_k = u_k \leftarrow t = u). \]

Trivial.

Q.E.D.

**Proposition 11.** If \( f : X_1 \times \cdots \times X_n \to Y \) is a function in \( \mathcal{M} \), its interpretation in \( \mathcal{N}_{af} \) is a function \( f : \downarrow X_1 \times \cdots \times \downarrow X_n \to \downarrow Y \).

Indeed, let \( f', f'' : \mathcal{M}^n \to \mathcal{M} \) be any two functionals which are extensions of the function \( f \) to the whole of \( \mathcal{M}^n \). By proposition 10(ii), we have :

\[ l \models (\forall x_1 \in \downarrow X_1) \ldots (\forall x_k \in \downarrow X_k)(f'(x_1, \ldots, x_k) = f''(x_1, \ldots, x_k)). \]

Q.E.D.

An important example is the set \( 2 = \{0, 1\} \) equipped with the trivial boolean functions, written \( \land, \lor, \neg \). The extension to \( \mathcal{N}_{af} \) of these operations gives a structure of Boolean algebra on \( \downarrow 2 \).

It is called the *characteristic Boolean algebra* of the model \( \mathcal{N}_{af} \).

**Conservation of well-foundedness**

Theorem 12 says that every well founded relation in the ground model \( \mathcal{M} \), gives a well founded relation in the realizability model \( \mathcal{N} \).

**Theorem 12.**

Let \( f : \mathcal{M}^2 \to 2 \) be a functional defined in the ground model \( \mathcal{M} \) such that \( f(x, y) = 1 \) is a well founded relation on \( \mathcal{M} \). Then, for every formula \( F[x] \) of ZF with parameters in \( \mathcal{M} \):

\[ Y \models \exists y \forall x(f(x, y) = 1 \iff F[x]) \to F[y] \to \forall y F[y] \]

with \( Y = AA \) and \( A = \lambda a \lambda f(f)(a) af \) (or \( A = (W)(B)(BW)(C)B \)).

Let us fix \( b \in X \) and let \( \xi \models \forall y(\forall x(f(x, y) = 1 \iff F[x]) \to F[y]) \). We show, by induction on \( b \), following the well founded relation \( f(x, y) = 1 \), that \( Y \star \xi \star \pi \in \perp \) for every \( \pi \in \| F[b] \| \).

Thus, suppose that \( \pi \in \| F[b] \| \); since \( Y \star \xi \star \pi > \xi \star Y \xi \star \pi \), we need to show that \( \xi \star Y \xi \star \pi \in \perp \).

By hypothesis, we have \( \xi \models \forall x(f(x, b) = 1 \iff F[x]) \to F[b] \); thus, it suffices to show that :

\[ Y \xi \models f(a, b) = 1 \iff F[a] \] for every \( a \in X \). This is clear if \( f(a, b) \neq 1 \), by definition of \( \iff \).

If \( f(a, b) = 1 \), we must show \( Y \xi \models F[a] \), i.e. \( Y \star \xi \star \varnothing \in \perp \) for every \( \varnothing \in \| F[a] \| \). But this follows from the induction hypothesis.

Q.E.D.

**Remarks.**

i) If the function \( f \) is only defined on a set \( X \) in the ground model \( \mathcal{M} \), we can apply theorem 12 to the
extension \( f' \) of \( f \) defined by \( f'(x, y) = 0 \) if \((x, y) \in X^2\).

This shows that, in the realizability model \( \mathcal{N} \), the binary relation \( f(x, y) = 1 \) is well founded on \( \Box X \).

ii) We can use theorem 12 to show that the axiom of foundation of \( ZF_\varepsilon \) is realized in \( \mathcal{N}_{\text{df}} \).

Indeed, let us define \( f : \mathcal{M}^2 \to 2 \) by setting \( f(x, y) = 1 \iff \exists z((x, z) \in y) \). The binary relation \( f(x, y) = 1 \) is obviously well founded in \( \mathcal{M} \). Now, we have \( \models \forall x \forall y(f(x, y) \neq 1 \to x \not\in y) \) because \( \pi \in \Box \not\in y \Rightarrow f(x, y) = 1 \). Thus, the relation \( x \not\in y \) is stronger than the relation \( f(x, y) = 1 \), which is well founded in \( \mathcal{N}_{\text{df}} \) by theorem 12.

1.6 Integers

Let \( \phi, \alpha \in \Lambda \) and \( n \in \mathbb{N} \); we define \((\phi)^n \alpha \in \Lambda \) by setting \((\phi)^0 \alpha = \alpha \); \((\phi)^{n+1} \alpha = (\phi)(\phi)^n \alpha \).

For \( n \in \mathbb{N} \), we define \( n = (\sigma)^n 0 \) with \( 0 = \text{Kl} \) and \( \sigma = (\text{BW})(\text{B}) \).

\( n \) is “the integer \( n \)” and \( \sigma \) the “successor” in combinatory logic.

The essential property of \( 0 \) and \( \sigma \) is: \( 0 \star \phi \star \alpha \star \pi > \alpha \star \pi \); \( \sigma \star \nu \star \phi \star \alpha \star \pi > \nu \star \phi \star \alpha \star \pi \).

We set \( \mathbb{N}_{\text{df}} = \{(n, n \star \pi); n \in \mathbb{N}, \pi \in \Pi \} \); it is shown below that \( \mathbb{N}_{\text{df}} \) is the set of integers of the realizability model \( \mathcal{N}_{\text{df}} \).

We define the quantifier \( \forall x^{\text{int}} \) as follows:

\[
\| \forall x^{\text{int}} F[x] \| = \{n \star \pi; n \in \mathbb{N}, \pi \in \| F[n] \| \}.
\]

which means intuitively:

\[
\| \forall x^{\text{int}} F[x] \| = \| \forall n^{\mathbb{N}}(\{n\} \to F[n]) \|.
\]

The formulas \( \forall x^{\text{int}} F[x] \) and \( \forall x(x \not\in \mathbb{N}_{\text{df}} \to F[x]) \) are interchangeable, as is shown in the:

**Lemma 13.**

\[
\lambda x \lambda n \lambda y(y)(x)n \models \forall x^{\text{int}} F[x] \to \forall x^{\text{int}} \neg \neg F[x]; \\
\lambda x \lambda n(\text{cc})(x)n \models \forall x^{\text{int}} \neg \neg F[x] \to \forall x^{\text{int}} F[x]; \\
\| \forall x^{\text{int}} \neg \neg F[x] \| = \| \forall x(\neg F[x] \to x \not\in \mathbb{N}_{\text{df}}) \|.
\]

Immediate.

Q.E.D.

**Lemma 14.**

i) \( K \models \forall x(x \not\in \Box \mathbb{N} \to x \not\in \mathbb{N}_{\text{df}}) \).

ii) \( \lambda x(x)0 \models 0 \not\in \mathbb{N}_{\text{df}} \to \bot \); \( \lambda f \lambda x(f)(\sigma)x \models \forall y^{\mathbb{N}} ((y + 1) \not\in \mathbb{N}_{\text{df}} \to y \not\in \mathbb{N}_{\text{df}}) \).

iii) \( I \models \forall x^{\text{int}} (\forall y^{\mathbb{N}}(F[y] \to F[y + 1]), F[0] \to F[x]) \) for every formula \( F[x] \) of \( ZF_\varepsilon \).

i) and ii) Immediate.

iii) Let \( n \in \mathbb{N} \), \( \phi \models \forall y^{\mathbb{N}}(F[y] \to F[y + 1]), \alpha \models F[0] \) et \( \pi \in \| F[n] \| \). We must show:

\( n \star \phi \star \alpha \star \pi \in \bot \), i.e., by lemma 15, \((\phi)^n \alpha \star \pi \in \bot \).

But it is clear, by recurrence on \( n \), that \((\phi)^n \alpha \models F[n] \) for every \( n \in \mathbb{N} \).

Q.E.D.

Lemma 14(i) shows that \( \mathbb{N}_{\text{df}} \) is a subset of \( \Box \mathbb{N} \).

But it is clear that \( \Box \mathbb{N} \) contains 0 and is closed by the function \( n \mapsto n + 1 \).

Now, by lemma 14(ii) and (iii), \( \mathbb{N}_{\text{df}} \) is the smallest subset of \( \Box \mathbb{N} \) which contains 0 and is closed by the function \( n \mapsto n + 1 \). Therefore:

\( \mathbb{N}_{\text{df}} \) is the set of integers of the model \( \mathcal{N}_{\text{df}} \).

The following lemmas 15 and 16 will be used in section 3 (proof of lemma 39).
Lemma 15.
Let $O, \zeta \in \Lambda$ be such that : $O \ast \phi \ast \alpha \ast \pi \gg \alpha \ast \pi$ and $\zeta \ast \ast \phi \ast \alpha \ast \pi \gg \ast \phi \ast \phi \alpha \ast \pi$
for every $\alpha, \nu, \phi \in \Lambda$ and $\pi \in \Pi$.
Then, for every $n \in \mathbb{N}$, $\alpha, \zeta, \phi \in \Lambda$ and $\pi \in \Pi$ :

i) $(\zeta)^n O \ast \phi \ast \alpha \ast \pi \gg (\phi)^n \alpha \ast \pi$; in particular, $n \ast \phi \ast \alpha \ast \pi \gg (\phi)^n \alpha \ast \pi$.

ii) $(\zeta)^n O \ast CB\phi \ast \zeta \ast \alpha \ast \pi \gg \zeta \ast (\phi)^n \alpha \ast \pi$.

i) Proof by recurrence on $n$ ; this is clear if $n = 0$ ; if $n = m + 1$, we have :
$\zeta \ast (\zeta)^m O \ast \phi \ast \alpha \ast \pi \gg (\zeta)^m O \ast \phi \ast \phi \alpha \ast \pi \gg (\phi)^m (\phi)\alpha \ast \pi$ by the recurrence hypothesis.
The particular case is $O = 0, \zeta = \sigma$.

ii) By (i), we have $(\zeta)^n O \ast CB\phi \ast \zeta \ast \alpha \ast \pi \gg (CB\phi)^n \zeta \ast \alpha \ast \pi$.
We now show, by recurrence on $n$, that $(CB\phi)^n \zeta \ast \alpha \ast \pi \gg (\phi)^n \alpha \ast \pi$. This is clear if $n = 0$ ; if $n = m + 1$, we have $(CB\phi)^n \zeta \ast \alpha \ast \pi \gg CB\phi \ast (CB\phi)^m \zeta \ast \alpha \ast \pi \gg CB\phi \ast (CB\phi)^m \zeta \ast \alpha \ast \pi \gg (CB\phi)^m \zeta \ast \phi \alpha \ast \pi \gg \zeta \ast (\phi)^m (\phi)\alpha \ast \pi$ (by the recurrence hypothesis).
Q.E.D.

Lemma 16.
Let $\Omega, \Sigma \in \Lambda$ be such that : $\Omega \ast \delta \ast \phi \ast \alpha \ast \pi \gg \alpha \ast \pi$ and $\Sigma \ast \nu \ast \delta \ast \phi \ast \alpha \ast \pi \gg \nu \ast \delta \ast \phi \ast \phi \alpha \ast \pi$
for every $\alpha, \delta, \nu, \phi \in \Lambda$ and $\pi \in \Pi$. For instance : $\Omega = (K)(K)l ; \Sigma = (B)(BW)(B)B$.
Then, for every $n \in \mathbb{N}$, $\alpha, \delta, \zeta, \phi \in \Lambda$ and $\pi \in \Pi$ :

i) $(\Sigma)^n \Omega \ast \delta \ast \phi \ast \alpha \ast \pi \gg (\phi)^n \alpha \ast \pi$.

ii) $(\Sigma)^n \Omega \ast \delta \ast CB\phi \ast \zeta \ast \alpha \ast \pi \gg \zeta \ast (\phi)^n \alpha \ast \pi$.

Same proof as lemma 15.
Q.E.D.

2 The characteristic Boolean algebra $\mathbb{J}$

2.1 Function symbols

Let us now define the principal function symbols commonly used in the sequel. As explained before, they are defined in the ground model $\mathcal{M}$ and are immediately extended to the realizability model $\mathcal{N}_{df}$.

- The projections $pr_0 : X \times Y \rightarrow X$ and $pr_1 : X \times Y \rightarrow Y$ defined by :
$pr_0(x,y) = x, \quad pr_1(x,y) = y$
give, in $\mathcal{N}_{df}$, a bijection from $\mathbb{J}(X \times Y)$ onto $\mathbb{J}X \times \mathbb{J}Y$.

- We define, in $\mathcal{M}$, the function $app : Y^X \times X \rightarrow Y$ (read application) by setting :
$\text{app}(f,x) = f(x)$ for $f \in Y^X$ and $x \in X$.
This gives, in $\mathcal{N}_{df}$, an application $app : \mathbb{J}(Y^X) \times \mathbb{J}X \rightarrow \mathbb{J}Y$.
We shall write $f(x)$ for $\text{app}(f,x)$.

Theorem 17.
If $X \neq \emptyset$, then $I \models \forall f \mathbb{J}(Y^X) \forall g \mathbb{J}(Y^X) (\forall x \mathbb{J}X (\text{app}(f,x) = \text{app}(g,x)) \rightarrow f = g)$. In other words :
$I \models \text{the function app gives an injection from } \mathbb{J}(Y^X) \text{ into } (\mathbb{J}Y)^{\mathbb{J}X}$.
Proposition 19.

Let \( f, g \in Y^X, \xi \models \forall x^X (\text{app}(f, x) \neq \text{app}(g, x) \rightarrow \perp) \) and \( \pi \in \| f \neq g \rightarrow \perp \| \).

We must show \( \xi \models f \neq g \) \( \rightarrow \perp \). We choose \( a \in X \); then \( \xi \models (f(a) \neq g(a) \rightarrow \perp) \).

If \( f = g \), we have \( \| f(a) \neq g(a) \rightarrow \perp \| = \| f \neq g \rightarrow \perp \| = \| \perp \rightarrow \perp \| \). Hence the result.

If \( f \neq g \), we could choose \( a \) such that \( f(a) \neq g(a) \).

Then, \( \| f(a) \neq g(a) \rightarrow \perp \| = \| f \neq g \rightarrow \perp \| = \| \top \rightarrow \perp \| \). Hence the result.

Q.E.D.

- Let \( \text{sp} : \mathcal{M} \rightarrow \{0,1\} \) (read support) the unary function symbol defined by :
  \( \text{sp}(\phi) = 0 \); \( \text{sp}(x) = 1 \) if \( x \neq \phi \).

In the realizability model \( \mathcal{N}_{ad} \), we have \( \text{sp} : \mathcal{N} \rightarrow \mathcal{I} \).

- Let \( \mathcal{P} : \{0,1\} \times \mathcal{M} \rightarrow \mathcal{M} \) (read projection) the binary function symbol defined by :
  \( \mathcal{P}(0,x) = \emptyset \); \( \mathcal{P}(1,x) = x \).

In the realizability model \( \mathcal{N}_{ad} \), we have \( \mathcal{P} : \mathcal{I} \times \mathcal{M} \rightarrow \mathcal{M} \).

In the following, we shall write \( i x \) instead of \( \mathcal{P}(i,x) \).

When \( t, u \) are \( \ell \)-terms with values in \( \mathcal{I} \), we write \( t \leq u \) for \( t u = t \).

**Proposition 18.**

i) \( l \models \forall i^2 x(i(j) = (i \wedge j)x) \).

ii) \( l \models \forall i^2 x(i x = x \iff \text{sp}(x) \leq i) \).

iii) If \( \phi \in E \), then \( l \models \forall i^2 x(\forall x(f(x,\ldots,x) = \phi) \rightarrow \phi) \).

iv) If \( f : \mathcal{M}^n \rightarrow \mathcal{M} \) is a function symbol such that \( f(\phi,\ldots,\phi) = \phi \), then :

\[ l \models \forall j^2 \forall x_1 \ldots \forall x_n (f(x_1,\ldots,x_n) = f(j x_1,\ldots,j x_n)) \]

v) \( l \models \forall i^2 x(i x \neq i y ightarrow \forall y(y \neq i x)) \) and therefore \( \mathcal{I} \models \forall i^2 x(i x \neq i y) \).

Trivial.

Q.E.D.

**Remark.** Proposition 18(v) shows that, in the realizability model \( \mathcal{N} \), every non empty individual has support 1.

Because of property (iv), we shall define, as far as possible, each function symbol \( f \) in \( \mathcal{M} \), so that to have \( f(\phi,\ldots,\phi) = \phi \).

- Thus, let us change the ordered pair \( (x,y) \) by setting \( (\phi,\phi) = \phi \). Then, we have :

\[ l \models \forall i^2 x \forall y(i x y = (i x, i y)) \]

- We define the binary function symbol \( \sqcup : \mathcal{M}^2 \rightarrow \mathcal{M} \) by setting : \( \sqcup a b = a \sqcup b \).

**Remark.** The extension to \( \mathcal{N} \) of this operation is neither the union for the \( \varepsilon \)-membership, nor the union for the \( \varepsilon \)-membership.

**The operation \( \sqcup_i \)**

Let \( E \in \mathcal{M} \) be such that \( \phi \in E \). In \( \mathcal{M} \), we define \( \sqcup_i E \) for \( i \in 2 \) by setting :

\( \sqcup_0 E = \sqcup \{ \phi \} \times \Pi \); \( \sqcup_1 E = E \times \Pi \).

In this way, we have now defined \( \sqcup_i E \) in \( \mathcal{N} \), for every \( i \in \mathcal{I} \).

**Proposition 19.**

i) \( l \models \forall i^2 x \forall y(i x \sqcup y = i x \sqcup i y) \).

ii) \( l \models \forall j^2 x j^2 x((i \wedge j)x = i x \sqcup j x) \).

iii) \( l \models \forall j^2 x j^2 x \forall y y \forall z(i j = 0, z = i x \sqcup j y \iff i z = i x) \).
\[ l \models \forall i^{12} \forall j^{12} \forall x \forall y \forall z (i \land j = 0, z = i \cup j y \iff j z = j y). \]

\[ iv) l \models \forall i^{12} \forall j^{12} \forall x^{12} \forall y^{12} \forall z (i \land j = 0, z = i \cup j y \iff z \varepsilon \mathbb{1}_{i \lor j} E). \]

Trivial.

Q.E.D.

**Proposition 20.**

If \( \phi \in E, E' \), the following formulas are realized:

i) \( \mathbb{1}_i E \) increases with \( i \). In particular, \( \mathbb{1}_i E \subseteq \mathbb{1}_E. \)

ii) The \( \varepsilon \)-elements of \( \mathbb{1}_i E \) are the \( ix \) for \( x \varepsilon \mathbb{1}_E. \)

iii) The \( \varepsilon \)-elements of \( \mathbb{1}_i E \) are those of \( \mathbb{1} E \) such that \( sp(x) \leq i. \)

iv) The only \( \varepsilon \)-element common to \( \mathbb{1}_i E \) and \( \mathbb{1}_{1-i} E \) is \( \emptyset. \)

v) If \( i \land j = 0, \) then the application \( x \mapsto (i x, j x) \) is a bijection from \( \mathbb{1}_{i \lor j} E \) onto \( \mathbb{1}_i E \times \mathbb{1}_j E. \)

The inverse function is \( (x, y) \mapsto x \cup y. \)

vi) \( \mathbb{1}_i (E \times E') = \mathbb{1}_i E \times \mathbb{1}_i E'. \)

We check immediately i), ii), iii), iv) below:

i) \( l \models \forall i^{12} \forall j^{12} \forall x (i \land j = i \mapsto (x d \mathbb{1}_j E \rightarrow x d \mathbb{1}_i E)). \)

ii) \( l \models \forall i^{12} \forall x^{12} (i x \in \mathbb{1}_i E) ; l \models \forall i^{12} \forall x^{12} (i x \neq x \rightarrow x d \mathbb{1}_j E). \)

iii) \( l \models \forall i^{12} \forall x^{12} (x d \mathbb{1}_i E \rightarrow i \land sp(x) \neq sp(x)) ; l \models \forall i^{12} \forall x^{12} (i \land sp(x) \neq sp(x) \rightarrow x d \mathbb{1}_j E); \)

iv) \( l \models \forall i^{12} \forall x^{12} (i x = (1 - i) y \iff i x = \emptyset). \)

v) By proposition 19(ii), we have \( ix \cup jx = (i v j)x = x \) if \( x \varepsilon \mathbb{1}_{i \lor j} E. \)

By proposition 19(iii,iv), if \( x, y \varepsilon \mathbb{1} E, \) there exists \( z \varepsilon \mathbb{1}_{i \lor j} E \) such that \( i z = i x, j z = j y, \) namely \( z = i x \cup j y. \)

vi) By proposition 18(iv), we have \( l \models \forall i^{12} \forall x \forall y (i (x, y) = (i x, i y)). \)

Q.E.D.

**Proposition 21.** Let \( E, E' \in \mathcal{M} \) be such that \( \phi \in E, E' \) and \( E \) is equipotent with \( E'. \) Then:

\( l \models \forall i^{12} (\mathbb{1}_i E \) is equipotent with \( \mathbb{1}_i E'). \)

Let \( \phi \) be, in \( \mathcal{M} \), a bijection from \( E \) onto \( E' \), such that \( \phi(\emptyset) = \emptyset. \) Then \( \phi \) is, in \( \mathcal{N} \), a bijection from \( \mathbb{1} E \) onto \( \mathbb{1} E'. \) But we have immediately: \( l \models \forall i^{12} \forall x^{12} (\phi(i x) = i \phi(x)). \) This shows that \( \phi \) is a bijection from \( \mathbb{1}_i E \) onto \( \mathbb{1}_i E'. \)

Q.E.D.

### 2.2 Some general theorems

Theorems 22 to 30, which are shown in this section, are valid in every realizability model.

In the ground model \( \mathcal{M} \), which satisfies \( ZF + V = L \), we denote by \( \kappa \) the cardinal of \( \Lambda \cup \Pi \cup \mathbb{N} \) (which we shall also call the cardinal of the algebra \( \mathcal{A} \)) and by \( \kappa_+ = \mathcal{P}(\kappa) \) the power set of \( \kappa. \)

**Theorem 22.**

Let \( \forall \overline{x} \forall y F[\overline{x}, y] \) be a closed formula of \( ZF_e \) with parameters in \( \mathcal{M} \) (where \( \overline{x} = (x_1, \ldots, x_n) \)). Then, there exists in \( \mathcal{M} \), a functional \( f_F : \kappa \times \mathcal{M}^n \rightarrow \mathcal{M} \) such that:

i) If \( \overline{a}, b \in \mathcal{M} \) and \( \xi \models F[\overline{a}, b] \), then there exists \( \alpha \in \kappa \) such that \( \xi \models F[\overline{a}, f_F(\alpha, \overline{a})]. \)

ii) \( \mathcal{C}l \models \forall \overline{x} \forall y \{ F[\overline{x}, y] \rightarrow \exists \overline{y}^{\kappa} F[\overline{x}, f_F(\overline{y}, \overline{x})] \}. \)
i) Let \( \xi \mapsto \alpha_\xi \) be an injection from \( \Lambda \) into \( \kappa \). Using the principle of choice in \( \mathcal{M} \) (which satisfies \( V = \text{L} \)), we can define a functional \( f_F : \kappa \times \mathcal{M}^n \to \mathcal{M} \) such that, in \( \mathcal{M} \), we have:
\[
\forall x \forall y (\forall \xi \in \Lambda) \left( \xi \vdash F(x, y) \Rightarrow \xi \vdash F(x, f_F(\alpha_\xi, \vec{x})) \right).
\]

ii) Let \( \xi \vdash F(\vec{a}, b) \), \( \eta \vdash \forall \forall \forall \forall \forall \forall F(\vec{a}, f_F(\nu, \vec{a})) \) and \( \pi \in \Pi \). Thus, we have \( \eta \vdash \neg F(\vec{a}, f_F(\alpha_\xi, \vec{a})) \);
by definition of \( f_F \), we have \( \xi \vdash F(\vec{a}, f_F(\alpha_\xi, \vec{a})) \). Therefore \( \eta \star \xi \star \pi \in \perp \), and \( \perp \star \xi \star \eta \star \pi \in \perp \).
Q.E.D.

**Remark.** The function \( f_F \) is a kind of weak choice function for the relation \( F(x, y) \); given \( \vec{x} \), it does not give exactly a witness \( y \) such that \( F(\vec{x}, y) \), but a family indexed by \( \kappa \) in which there is such a witness.

**Subsets of \( \kappa^+ \)**

**Theorem 23.** Let \( \forall x \forall y \forall z \ F[x, y, z] \) be a closed formula of \( \text{ZF}_\ell \), with parameters in \( \mathcal{M} \).
Then, there exists, in \( \mathcal{M} \), a functional \( \beta_F : \mathcal{M} \to \kappa^+ \) such that:
\[
W \vdash \forall \exists \forall \forall y \forall y' \forall \forall \forall \forall F(x, y, z), F(x, y', z) \to y = y' \to \perp,
\]
\[
\xi \vdash F(\vec{a}, b), \quad \eta \vdash \text{sp}(\alpha) \not\equiv i \\
\quad \ni \quad \pi \in \Pi.
\]
By theorem 22(iii), there exists, in \( \mathcal{M} \), a functional \( g : \kappa \times \mathcal{M}^2 \to \mathcal{M} \) such that:
\[
(*) \quad \text{If } a, b, c \in \mathcal{M} \text{ and } \xi \vdash F[a, b, c], \text{ there exists } \alpha \in \kappa \text{ such that } \xi \vdash F[\alpha, g(\alpha, a, c), c].
\]

Using the principle of choice in \( \mathcal{M} \), we define a functional \( \beta_F : \mathcal{M} \to \kappa^+ \) such that:
for every \( \alpha \in \kappa \) and \( c \in \mathcal{M} \), we have \( \beta_F(c) \not\equiv g(\alpha, \varnothing, c) \).
This is possible since \( \kappa^+ \) is of cardinal \( > \kappa \).

Now let:
\[
a, c \in \mathcal{M}, \quad i \in \{0, 1\}, \quad \phi \vdash \forall x \forall y \forall y' \forall \forall \forall \forall F(x, y, c), F(x, y', c), y \not\equiv y' \to \perp,
\]
\[
\xi \vdash F(\vec{a}, b, i \beta_F(c), c), \quad \eta \vdash \text{sp}(\alpha) \not\equiv i \\
\quad \ni \quad \pi \in \Pi.
\]
We must show that \( W \star \phi \star \xi \star \eta \star \pi \in \Pi \), that is \( \phi \star \xi \star \eta \star \pi \in \Pi \).

We set \( b = i \beta_F(c) \) and therefore, we have \( \xi \vdash F[a, b, c] \).

Thus, by (*), we have \( \xi \vdash F[a, g(\alpha, a, c), c] \) for some \( \alpha \in \kappa \).

Let us show that \( \| b \not\equiv g(a, a, c) \| \equiv \| \text{sp}(a) \not\equiv i \| \); there are three possible cases:
If \( i = 0 \), then \( \| \text{sp}(a) \not\equiv i \| = \| 0 \not\equiv 0 \| = \Pi \), hence the result.
If \( i = 1 \) and \( a \not\equiv \varnothing \), then \( \| \text{sp}(a) \not\equiv i \| = \| 1 \not\equiv 1 \| = \Pi \), hence the result.
If \( i = 1 \) and \( a = \varnothing \), then:
\[
\| b \not\equiv g(a, a, c) \| = \| i \beta_F(c) \not\equiv g(\alpha, a, c) \| = \| \beta_F(c) \not\equiv g(\alpha, \varnothing, c) \| = \| \perp \| = \varnothing,
\]
by definition of \( \beta_F \), hence the result.

It follows that \( \eta \vdash b \not\equiv g(a, a, c) \). Now, we have seen that:
\( \xi \vdash F[a, b, c] \) and \( \xi \vdash F[a, g(\alpha, a, c), c] \).

Therefore, by hypothesis on \( \phi \), we have \( \phi \star \xi \star \eta \star \pi \in \Pi \).
Q.E.D.

**Remark.** Theorem 23 is crucial for the applications in the sequel. A perhaps more intuitive reformulation is given in corollary 24(i).

**Corollary 24.** If \( \varnothing \in E \), then the following formulas are realized:
i) \( \forall i \exists j \exists (i, j \not\equiv j \not\equiv i) \) on \( \downarrow \kappa^+ \).
ii) \( \forall i \exists j \exists (i \not\equiv j \not\equiv i) \) on \( \downarrow \kappa^+ \).
iii) \( \forall i \exists j \exists (i, j \not\equiv i \wedge j = 0 \to (i, j \not\equiv j \not\equiv i)) \) on \( \downarrow \kappa^+ \).

**Remarks.**

\( \cup \) is the symbol for disjoint union.
The notation \( \bigcup \bigl[ j \in \mathbb{N}; j \neq i \bigr] E \) denotes any individual \( X \) of \( \mathcal{N} \) such that:
\[
\mathcal{N} \models \forall x (x \in X \rightarrow \exists j^{\mathbb{N}} (j \neq i \wedge x \in j E)).
\]
i) We apply theorem 23, with the formula \( F[x, y, z] \equiv (x, y) \in z \).
In the realizabilibity model \( \mathcal{N} \), we have \( \beta_F : \mathcal{N} \to \mathbb{I} \).
Let \( z_0 \) be, in \( \mathcal{N} \), a surjective function onto \( \mathbb{I} \).
We have \( \beta_F(z_0) \in \mathbb{I} \), and therefore \( i \beta_F(z_0) \in \mathbb{I} \).
If \( x_0 \) is such that \( (x_0, i \beta_F(z_0)) \in z_0 \), then \( sp(x_0) \geq i \) by theorem 23.
Therefore, we have \( x_0 \in j E \Rightarrow j \geq i \), by proposition 20(iii).
ii) It is a trivial consequence of (i).
iii) We take \( E = \kappa_+ \); since \( i, j \neq 0, i \wedge j = 0 \), we have \( i, j \neq i \vee j \); by (i), there is no surjection from \( \mathbb{I} \) onto \( \mathbb{I} \).
Now, since \( i \vee j = 0 \), \( \mathbb{I} \) is equipotent with \( \mathbb{I} \) by proposition 20(v).
Moreover, \( \emptyset \) is the only \( e \)-element common to \( \mathbb{I} \) and \( \mathbb{I} \) by proposition 20(iv).
But these sets contain a countable subset by theorem 26. It follows that \( \mathbb{I} \cup \mathbb{I} \) is equipotent with \( \mathbb{I} \).
\[\text{Q.E.D.}\]

**Theorem 25.** There is a function symbol \( f \) such that \( \models (\forall y \in \mathbb{I})(\exists x \in \mathbb{I})(y \equiv f(x)) \).

*Roughly:* \( \models (f \text{ is a surjection from } \mathbb{I} \text{ onto } 2^\mathbb{I}) \).

**Reminder.** \( x \leq y \) is \( \forall z (x = y \rightarrow z \in x) \); \( x = x \) is \( \forall x \forall y (x \leq y \wedge y \leq x) \).

In the ground model \( \mathcal{M} \), we have \( \kappa \geq \text{card}(\Pi) \); thus, there exists a bijection \( f \) from \( \kappa = 2^\kappa \)
to \( \mathcal{P}(\kappa \times \Pi) \). Therefore, \( f \) is a function symbol which is a bijection from \( \mathbb{I} \) onto \( \mathcal{P}(\kappa \times \Pi) \).

In the ground model \( \mathcal{M} \), we define \( \phi : \mathcal{M} \to \mathcal{P}(\kappa \times \Pi) \) by \( \phi(x) = x \cap (\kappa \times \Pi) \).

In \( \mathcal{N} \), we have \( \phi : \mathcal{N} \to \mathcal{P}(\kappa \times \Pi) ; \models \forall x (\phi(x) = \phi(x)) \).

Now, we check immediately that:

i) \( \models \forall y \forall x \exists \mathcal{P}(\kappa \times \Pi) (v \in \mathcal{P}(\kappa \times \Pi) \rightarrow v \in \mathcal{P}(\kappa \times \Pi)) \) because \( v \in \mathcal{P}(\kappa \times \Pi) \) for all \( a \in \mathcal{P}(\kappa \times \Pi) \).

ii) \( \models \forall x \forall v \exists \mathcal{P}(\kappa \times \Pi) (v \in \mathcal{P}(\kappa \times \Pi) \rightarrow v \in \mathcal{P}(\kappa \times \Pi)) \) because \( v \in \mathcal{P}(\kappa \times \Pi) \) for all \( v \in \kappa \).

From (i), it follows that \( \mathcal{P}(\kappa \times \Pi) \) is, in \( \mathcal{N} \), a set of \( e \)-subsets of \( \mathcal{P}(\kappa \times \Pi) \); from (ii), it follows that it contains at least one representative for each equivalence class for \( \equiv \).

It follows that \( f \) has the desired properties.
\[\text{Q.E.D.}\]

**Theorem 26.** Let \( E \in \mathcal{M} \) be infinite and such that \( \phi \in E \). Then we have:
\[\models \forall i^{\mathbb{N}} (i \neq 0 \rightarrow \text{there exists an injection from } \mathbb{N} \text{ into } j E) \]

In \( \mathcal{M} \), let \( \phi : \mathbb{N} \to (E \setminus \emptyset) \) be injective. In \( \mathcal{N} \), we have \( \phi : \mathbb{N} \to \mathbb{I} \).

The desired function is \( n \mapsto i \phi(n) \). Indeed, we have:
\[\models \forall i^{\mathbb{N}} \forall m^{\mathbb{N}} (i \neq 0 \rightarrow i \phi(m + n + 1) \neq i \phi(m)) \]

This shows that the restriction of this function to \( \mathbb{N} \) (the set of integers of \( \mathcal{N} \)) is injective.
\[\text{Q.E.D.}\]

**Theorem 27.** \( \models \forall i^{\mathbb{N}} (i \neq 0, i \neq 1 \rightarrow (\mathbb{I} \text{ cannot be well ordered})) \).
Let \( i \in 2, i \neq 0,1 \); then, \( I_i \kappa_+ \) and \( I_{1-i} \kappa_+ \) are infinite (theorem 26) and \( \subseteq I_+ \) by proposition 20(i). But there exists no surjection from \( I_i \kappa_+ \) onto \( I_{1-i} \kappa_+ \), neither from \( I_{1-i} \kappa_+ \) onto \( I_i \kappa_+ \), by corollary 24.

Q.E.D.

**Remark.** It is probably useful to make clear what a well ordering is in this non extensional context. The formula \( (R \text{ is a strict well ordering on } X) \) is the conjunction of:
\[
(\forall x, y, z \in X) \left( (x, y) \in R, (y, z) \in R \implies (x, z) \in R \right),
\]
\[
(\forall x, y \in X) \left( x \neq y \implies (x, y) \in R \vee (y, x) \in R \right)
\]
(i.e. \( R \) is a strict total order) ; \( (\forall Y \subseteq X) (\forall x \in Y) (\exists y \in Y) (\exists z \in Y) ((z, y) \in R) \) (i.e. \( R \) is well founded).

Theorem 27 says that, if the Boolean algebra \( \mathcal{Z}2 \) is not trivial, then \( \mathcal{Z}k_+ \) is not well orderable. On the other hand, it can be shown that, if this Boolean algebra is trivial, then the realizability model \( \mathcal{R} \) is an extension by forcing of the ground model \( \mathcal{M} \). In this case, it is well known that \( \mathcal{R} \) itself can be well ordered (we suppose that the ground model \( \mathcal{M} \) satisfies \( ZF + V = L \)).

Note also that, even if there is a non well orderable set in \( \mathcal{R} \), we do not know if the underlying model of \( ZF \) satisfies \( AC \) or not.

**A strict order on \( I_k_+ \)**

A binary relation \( < \) on \( X \) is a *strict order* if it is transitive \( (x < y, y < z \implies x < z) \) and antireflexive \( (x \not< x) \). This strict order is called *total* if we have : \( x < y \) or \( y < x \) or \( x = y \).

If \( (X_0, <_0), (X_1, <_1) \) are two strictly ordered sets, then the *strict order product* \( < \) on \( X_0 \times X_1 \) is defined by : \( (x_0, x_1) < (y_0, y_1) \iff x_0 < y_0 \) and \( x_1 < y_1 \).

**Lemma 28.** The strict order product of \( <_0, <_1 \) is well founded if and only if one of the strict orders \( <_0, <_1 \) is well founded.

Proof of \( \Rightarrow \) : by contradiction ; if \( <_0 \) and \( <_1 \) are not well founded, we have :
\[
\forall y_0 \left( \forall x_0 (x_0 <_0 y_0 \rightarrow F_0[x_0]) \rightarrow F_0[y_0] \right); \neg F_0[b_0];
\]
\[
\forall y_1 \left( \forall x_1 (x_1 <_1 y_1 \rightarrow F_1[x_1]) \rightarrow F_1[y_1] \right); \neg F_1[b_1];
\]
for some formulas \( F_0, F_1 \) and some individuals \( b_0, b_1 \). It follows that :
\[
\forall y_0 \forall y_1 \left( \forall x_0 \forall x_1 (x_0 <_0 y_0, x_1 <_1 y_1 \rightarrow G[x_0, x_1]) \rightarrow G[y_0, y_1] \right); \neg G[b_0, b_1]
\]
where \( G[x_0, x_1] \equiv F_0[x_0] \vee F_1[x_1] \).

Proof of \( \Leftarrow \) : suppose that \( <_0 \) is well founded and let \( G[x_0, x_1] \) be any formula.
Let \( F[x_0] \equiv \forall x_1 G[x_0, x_1] \). We have to prove \( \forall y_0 \forall y_1 G[y_0, y_1] \), i.e. \( \forall y_0 F[y_0] \) with the hypothesis 
\[
\forall y_0 \forall y_1 \left( \forall x_0 \forall x_1 (x_0 <_0 y_0, x_1 <_1 y_1 \rightarrow G[x_0, x_1]) \rightarrow G[y_0, y_1] \right).
\]
But this implies :
\[
\forall y_0 \left( \forall x_0 (x_0 <_0 y_0 \rightarrow F[x_0]) \rightarrow F[y_0] \right)
\]
and the result follows, because \( <_0 \) is well founded.

Q.E.D.

We denote by \( < \) a strict well ordering on \( k_+ \), in \( \mathcal{M} \) ; we suppose that its least element is \( \emptyset \) and that the cardinal of each proper initial segment is \( \leq k \).

This gives a binary function from \( k^2 \) into \( \{0, 1\} \), denoted by \( (x < y) \), which is defined as follows :
\( (x < y) = 1 \iff x < y \).

We can extend it to the realizability model \( \mathcal{N}_{\mathcal{M}} \), which gives a function from \( (k_+)^2 \) into \( 2 \).

**Lemma 29.** The following propositions are realized :
*If \( i \in 2, i \neq 0 \), then \( (x < y) = i \) is a strict ordering of \( I_i \kappa_+ \), which we denote by \( q_i \).*
*If \( i \) is an atom of the Boolean algebra \( \mathcal{Z}2 \), then this ordering is total.*
We have immediately:

i) \( \models \forall x^{\mathfrak{J}+} \forall y^{\mathfrak{J}+} \forall z^{\mathfrak{J}+} ((x \preceq y) \land (y \preceq z) \leq (x \preceq z));  \models \forall x^{\mathfrak{J}+} ((x \preceq x) = 0). \)

ii) \( \models \forall x^{\mathfrak{J}+} \forall y^{\mathfrak{J}+} \forall z^{\mathfrak{J}+} ((ix \preceq iy) \leq i). \)

iii) \( \models \forall x^{\mathfrak{J}+} \forall y^{\mathfrak{J}+} ((x \preceq y) = 0, (y \preceq x) = 0 \iff x = y). \)

It follows from (i) that, if \( i \neq 0, \) then \((x \preceq y) \geq i\) is a strict ordering relation on \( \mathfrak{J}+. \)

It follows from (ii), that this relation, restricted to \( \mathfrak{J}_i\), is equivalent to \((x \preceq y) = i. \)

Finally, it follows from (iii), that the relation \((x \preceq y) = i, \) restricted to \( \mathfrak{J}_i\), is total when \( i \) is an atom of \( \mathfrak{J}. \)

Q.E.D.

**Lemma 30.** The following propositions are realized:

i) \( \forall i^{\mathfrak{J}+} (\text{the application } x \mapsto (ix, (1-i)x) \text{ is an isomorphism of strictly ordered sets from } (\mathfrak{J}_i, <) \text{ onto } (\mathfrak{J}_i^{\mathfrak{J}+}, <_{i}) \times (\mathfrak{J}_{1-i}^{\mathfrak{J}+}, <_{1-i})). \)

ii) \( \forall i^{\mathfrak{J}+} (\text{either } \mathfrak{J}_i \text{ or } \mathfrak{J}_{1-i} \text{ is a well founded ordered set}). \)

i) It follows from proposition 20(v), that the application \( x \mapsto (ix, (1-i)x) \) is a bijection from \( \mathfrak{J}_i^{\mathfrak{J}+} \) onto \( \mathfrak{J}_i \times \mathfrak{J}_{1-i}^{\mathfrak{J}+}. \) In fact, it is an *isomorphism* of ordered sets, since we have:

\[
\models \forall i^{\mathfrak{J}+} \forall x^{\mathfrak{J}+} \forall y^{\mathfrak{J}+} ((x \preceq y) = (ix \preceq iy) \lor ((1-i)x \preceq (1-i)y)) \text{ and therefore:}
\]

\[
\models \forall i^{\mathfrak{J}+} \forall x^{\mathfrak{J}+} \forall y^{\mathfrak{J}+} ((x \preceq y) = 1 \iff (ix \preceq iy) = i \land ((1-i)x \preceq (1-i)y) = 1-i).
\]

ii) By theorem 12, the relation \((x \preceq y) = 1\) is well founded on \( \mathfrak{J}_+. \) Thus, the result follows immediately from (i) and lemma 28.

Q.E.D.

### 2.3 \( \mathfrak{J} \) countable

In this section, we consider some consequences of the hypothesis: \( (\mathfrak{J} \text{ is countable}). \)

**Non extensional choice (NEAC) and dependent choice (DC)**

The formula \( \forall x \forall y \forall y' ((x, y) \in f, (x, y') \in f \rightarrow y = y') \) will be written \( \text{Func}(f) \)

(read: \( f \) is a function).

We recall that \( x \subseteq y \) is the formula \( \forall z (z \notin y \rightarrow z \notin x). \)

The formula \( \forall z \exists f (f \subseteq z \land \text{Func}(f) \land \forall x \forall y \exists y' ((x, y) \in z \rightarrow (x, y') \in f)) \)

is called the *non extensional axiom of choice* and denoted by NEAC.

It is easily shown [18] that \( \text{ZF} + \text{NEAC} \vdash \text{DC} \) (axiom of dependent choice). On the other hand, we have built, in [18], a model of \( \text{ZF} + \text{NEAC} + \neg \text{AC} ; \) and other such models will be given in the present paper. In all these models, \( \mathbb{R} \) is not well orderable.

**Theorem 31.**

There exists a closed c-term \( H \) such that \( \models (\mathfrak{J} \text{ is countable}) \rightarrow \text{NEAC}. \)

We apply theorem 22(ii) to the formula \((x, y) \in z. \) We get a function symbol \( g \) such that \( \models \forall x \forall y \forall z ((x, y) \in z \rightarrow \exists x^{\mathfrak{J}+} (x, g(v, x, z)) \in z) \).

Therefore, it suffices to prove NEAC in \( \text{ZF} \), by means of this formula and the additional hypothesis: \((\mathfrak{J} \text{ is countable}). \) Now, from this hypothesis, it follows that there exists a strict
well ordering \(<\) on \(\mathbb{J}\). Then, we can define the desired function \(f\) by means of the comprehension scheme:

\[(x, y) \in f \iff (x, y) \in z \land \exists \forall^\mathbb{J}(y = g(v, x, z) \land \forall a^\mathbb{J}(\alpha < v \to (x, g(\alpha, x, z)) \notin z)).\]

Intuitively, \(f(x) = g(v, x, z)\) for the least \(v \in \mathbb{J}\) such that \((x, g(v, x, z)) \in z\).

Q.E.D.

Subsets of \(\mathbb{R}\)

**Theorem 32.** \(\vdash (\mathbb{J} \text{ is countable}) \to\)

\(\forall\) every bounded above subset of the ordered set \((\mathbb{J}_+, <)\) is countable.

Every proper initial segment of the well ordering \(<\) on \(\kappa_+\) is of cardinal \(\kappa\). Thus, there exists a function \(\phi : \kappa \times \kappa_+ \to \kappa_+\) such that, for each \(x \in \kappa_+, x \neq \emptyset\), the function \(\alpha \mapsto \phi(\alpha, x)\) is a surjection from \(\kappa\) onto \(\{y \in \kappa_+ ; y < x\}\). Then, we have immediately:

\[\vdash \forall x^{\kappa_+} \forall y^{\kappa_+}(x < y \iff (\forall \alpha^{\kappa}(y < \phi(\alpha, x)) \to \bot)).\]

This shows that, in \(\mathcal{N}\), there exists a surjection from \(\mathbb{J}\), onto every subset of \(\mathbb{J}_+\) which is bounded from above for the strict ordering \(<\).

Thus, all these subsets of \(\mathbb{J}_+\) are countable, since \(\mathbb{J}\) is.

Q.E.D.

**Theorem 33.** \(\vdash (\mathbb{J} \text{ is countable}) \to\) there exists an injection from \(\mathbb{J}_+\) into \(\mathbb{R}\).

We have obviously \(\vdash (\mathbb{J} \text{ is countable} \to \mathbb{J}\text{ is countable})\), and therefore:

\(\vdash (\mathbb{J} \text{ is countable} \to (\mathbb{J}^2)^{\mathbb{J}} \text{ is equipotent to } \mathbb{R})\).

Now, by theorem 17, we have: \(\vdash\) (there is an injection from \(\mathbb{J}_+ = \mathbb{J}(2^{\kappa})\) into \((\mathbb{J}^2)^{\mathbb{J}}\)).

Q.E.D.

**Theorem 34.** The following formula is realized: \((\mathbb{J} \text{ is countable}) \to\) there exists an application \(i \mapsto X_i\) from the countable Boolean algebra \(\mathbb{J}\) into \(\mathcal{P}(\mathbb{R})\) such that:

i) \(X_0 = \{\emptyset\}; i \neq 0 \to X_i \text{ is uncountably infinite};\)

ii) \(X_i \times X_i \text{ is equipotent with } X_i;\)

iii) \(X_i \cap X_j = X_{i \land j} \text{ and therefore } i \leq j \to X_i \subseteq X_j;\)

iv) \(i \land j = 0 \to X_{i \lor j} \text{ is equipotent with } X_i \times X_j;\)

v) there exists a surjection from \(X_i\) onto \(\mathbb{R}\).

vi) if \(A\) is a subset of \(\mathbb{J}\) and if there is a surjection from \(\bigcup_{j \in A} X_j\) onto \(X_i\), then \(i \leq j\) for some \(j \in A\).

vii) if there is a surjection from \(X_j\) onto \(X_i\), then \(i \leq j;\)

viii) if \(i, j \neq 0, i \land j = 0\), then there is no surjection from \(X_i \cup X_j\) onto \(X_i \times X_j\).

For each \(i \in \mathbb{J}\), let us denote by \(X_i\) the image of \(\mathbb{J}_i\) in \(\mathbb{J}\) by the injection from \(\mathbb{J}_i\) into \(\mathbb{R}\), given by theorem 33.

i) The fact that \(X_i\) is infinite for \(i \neq 0\) is a consequence of theorem 26.

If \(i = 1\), \(X_i\) is uncountable by (v). If \(i \neq 0, 1\) and \(X_i\) is countable, then \(X_1 \cap X_i\) is infinite and thus, there exists a surjection from \(X_1 \cap X_i\) onto \(X_i\). This contradicts corollary 24.

ii) By proposition 20(vi), \(\mathbb{J}_i \times \mathbb{J}_j\) is equipotent with \(\mathbb{J}_i(\kappa_+^\mathbb{J})\), thus also with \(\mathbb{J}_i \times \mathbb{J}_j\) by proposition 21.

iii) If \(a \in \mathbb{J}_i\) and \(a \in \mathbb{J}_j\), then \(i a = a\), and therefore \((i \land j) a = j a = a\).
iv) This is proposition 20(v).

v) Application of theorem 25.

vi), vii), viii) Applications of corollary 24.

Q.E.D.

Theorem 34 is interesting only if the countable Boolean algebra $\mathcal{B}^2$ is not trivial. In this case, by theorems 27 and 33, $\mathbb{R}$ cannot be well ordered; the underlying model of ZF does not satisfy AC.

### 3 Collapsing $\mathcal{B}^\kappa$

In this section, we start with an arbitrary realizability algebra $\mathcal{A}$ and we build a new algebra $\mathcal{B}$ such that:

- $\mathcal{N}_\mathcal{B}$ realizes the formula: ($\mathcal{B}^\kappa$ is countable).
- The (countable) Boolean algebra $\mathcal{B}^2$ of the model $\mathcal{N}_\mathcal{B}$ is elementarily equivalent (for the language of rings) to the algebra $\mathcal{B}^2$ of $\mathcal{N}_\mathcal{A}$.

In the sequel, we shall consider two interesting cases: $\mathcal{B}^2$ is atomless; $\mathcal{B}^2$ has four $\varepsilon$-elements.

#### 3.1 Extending a realizability algebra

In the ground model $\mathcal{M}$, we consider a realizability algebra $\mathcal{A} = (\Lambda, \Pi, \Lambda \ast \Pi, \bot)$, the elementary combinators of which are denoted by $B, C, I, K, W, cc$ and the continuations $k_\pi$ for $\pi \in \Pi$. Let $\kappa$ be an infinite cardinal of $\mathcal{M}$, $\kappa \geq \text{card}(\Lambda \cup \Pi)$; we consider the tree (usually called $\kappa^{<\omega}$) of functions, the domain of which is an integer, with values in $\kappa$.

Let $P$ be the ordered set obtained by adding a least element $\emptyset$ to this tree.

$P$ is an inf-semi-lattice, the greatest element $\bot$ of which is the function $\emptyset$.

The greatest lower bound of $p, q \in P$, denoted by $pq$, is $p$ (resp. $q$) if $p, q \neq \emptyset$ and $q \subset p$ (resp. $p \subset q$). It is $\emptyset$ in every other case.

**Remark.** $P \setminus \{\emptyset\} = \kappa^{<\omega}$ is the ordered set used, in the method of forcing, to collapse (i.e. make countable) the cardinal $\kappa$.

We define a new realizability algebra $\mathcal{B}$ by setting:

- $\Lambda = \Lambda \times P$; $\Pi = \Pi \times P$; $\Lambda \ast \Pi = (\Lambda \ast \Pi) \times P$;
- $(\xi, p) \ast (\pi, q) = (\xi \ast \pi, pq)$; $(\xi, p) \ast (\pi, q) = (\xi \ast \pi, pq)$; $(\xi, p)(\eta, q) = (C \xi \eta, pq)$.
- $B = (B^*, 1)$; $C = (C^*, 1)$; $I = (I^*, 1)$; $K = (K^*, 1)$; $W = (W^*, 1)$; $cc = (cc^*, 1)$; $k_\pi = (k_\pi^*, 1)$.

The combinators $B^*, C^*, I^*, K^*, W^*, cc^*$, and the continuations $k_\pi^*$ are defined in such a way that we have, for every $\nu, \xi, \eta, \zeta \in \Lambda$ and $\pi \in \Pi$:

- $B^* \ast \nu \ast \xi \ast \eta \ast \zeta \ast \pi \Rightarrow \xi \ast \nu \ast C \eta \ast \zeta \ast \pi$;
- $C^* \ast \nu \ast \xi \ast \eta \ast \zeta \ast \pi \Rightarrow \zeta \ast \nu \ast \xi \ast \eta \ast \pi$;
- $I^* \ast \nu \ast \xi \ast \pi \Rightarrow \xi \ast \nu \ast \pi$;
- $K^* \ast \nu \ast \xi \ast \eta \ast \pi \Rightarrow \xi \ast \nu \ast \pi$;
- $W^* \ast \nu \ast \xi \ast \eta \ast \pi \Rightarrow \xi \ast \nu \ast \eta \ast \pi$;
- $k_\pi^* \ast \nu \ast \xi \ast \pi \Rightarrow \xi \ast \nu \ast k_\pi^* \ast \pi$;
- $cc^* \ast \nu \ast \xi \ast \pi \Rightarrow \xi \ast \nu \ast k_\pi^* \ast \pi$.

(reminder: the notation $\xi \ast \pi \Rightarrow \xi' \ast \pi' \Rightarrow \xi \ast \pi \in \bot \Rightarrow \xi' \ast \pi' \in \bot$).
Therefore, we set:

\[ B^* = \lambda n \lambda x y \lambda z (x n)(C) y z = ((C)(B)C)(B)(B)B ; \]

\[ C^* = \lambda n \lambda x y \lambda z (x n) y z = (C)(B)C ; \]

\[ I^* = \lambda n \lambda x n = C 1 ; \]

\[ K^* = \lambda n \lambda x y (x n) \; \text{or} \; (B)(B)K ; \]

\[ W^* = \lambda n \lambda x y (x n) y y = (C)(B)W ; \]

\[ k^*_n = \lambda n \lambda x (k_n)(x n) = (C)(B)k_n ; \]

\[ \text{cc}^*_n = \lambda n \lambda x (C)(B)k_n(x n) \]

We define, in \( \mathcal{M} \), a function symbol from \( P \times \mathbb{N} \) into \{0, 1\}, denoted by \( (p \prec n) \), by setting:

\( (p \prec n) = 1 \Leftrightarrow p \neq 0 \) and the domain of \( p \) is an integer \( \leq n \).

We define \( \bot \subseteq \mathcal{M} \), that we shall denote also by \( \bot \), as follows:

\( (\xi \star \pi, p) \in \bot \Leftrightarrow (\forall n \in \mathbb{N})((p \prec n) = 1 \Rightarrow \xi \star n \star \pi \in \bot) \) for \( p \in P \), \( \xi \in \Lambda \) and \( \pi \in \Pi \).

In particular, we have \( (\xi \star \pi, 0) \in \bot \) for any \( \xi \in \Lambda, \pi \in \Pi \).

We check now that \( \mathcal{B} \) is a realizability algebra:

- \( (\xi, p)(\eta, q) \star (\pi, r) \in \bot \Leftrightarrow (\xi, p)(\eta, q) \star (\pi, r) \in \bot \):

Suppose that \( (\xi \star \eta \star \pi, p q r) \in \bot \); we must show \( (\xi \star \eta \star \pi, p q r) \in \bot \) i.e. \( \xi \star \eta \star \pi \in \bot \) for \( (p q r \prec n) = 1 \). Now, we have \( \xi \star \eta \star \pi \in \bot \) by hypothesis.

- \( (B^*, 1) \star (\xi, p)(\eta, q)(\pi, r)(\pi, s) \in \bot \Rightarrow (\xi, p)(\eta, q)(\pi, r)(\pi, s) \in \bot \):

Suppose that \( (\xi, p)(\eta, q)(\pi, r)(\pi, s) \in \bot \) i.e. \( (\xi \star \eta)(\pi, r)(\pi, s) \in \bot \); we must show:

\( (B^* \star \xi \star \eta \star \pi, p q r s) \in \bot \) i.e. \( B^* \star \xi \star \eta \star \pi \in \bot \) for \( (p q r s \prec n) = 1 \). Now, we have:

\( B^* \star \xi \star \eta \star \pi \in \bot \) by hypothesis.

- \( (C^*, 1) \star (\xi, p)(\eta, q)(\pi, s) \in \bot \Rightarrow (\xi, p)(\eta, q)(\pi, s) \in \bot \):

Suppose that \( (\xi \star \eta \star \pi, p q r s) \in \bot \); we must show:

\( (C^* \star \xi \star \eta \star \pi, p q r s) \in \bot \) i.e. \( C^* \star \xi \star \eta \star \pi \in \bot \) for \( (p q r s \prec n) = 1 \). Now, we have:

\( C^* \star \xi \star \eta \star \pi \in \bot \) by hypothesis.

- \( (l^*, 1) \star (\xi, p)(\pi, r) \in \bot \Rightarrow (\xi, p)(\pi, r) \in \bot \):

Suppose that \( (\xi \star \eta, p q) \in \bot \); we must show:

\( (l^* \star \xi \star \eta, p q) \in \bot \) i.e. \( l^* \star \xi \star \eta \in \bot \) for \( (p q \prec n) = 1 \). Now, we have:

\( l^* \star \xi \star \eta \in \bot \) by hypothesis.

- \( (K^*, 1) \star (\xi, p)(\eta, q)(\pi, r) \in \bot \Rightarrow (\xi, p)(\eta, q)(\pi, r) \in \bot \):

Suppose that \( (\xi \star \eta \star \pi, p q r) \in \bot \); we must show:

\( (K^* \star \xi \star \eta \star \pi, p q r) \in \bot \) i.e. \( K^* \star \xi \star \eta \star \pi \in \bot \) for \( (p q r \prec n) = 1 \). Now, we have:

\( K^* \star \xi \star \eta \star \pi \in \bot \) by hypothesis.

- \( (W^*, 1) \star (\xi, p)(\eta, q)(\pi, r) \in \bot \Rightarrow (\xi, p)(\eta, q)(\pi, r) \in \bot \):

Suppose that \( (\xi \star \eta \star \pi, p q r) \in \bot \); we must show:

\( (W^* \star \xi \star \eta \star \pi, p q r) \in \bot \) i.e. \( W^* \star \xi \star \eta \star \pi \in \bot \) for \( (p q r \prec n) = 1 \). Now, we have:

\( W^* \star \xi \star \eta \star \pi \in \bot \) by hypothesis.

- \( (cc^*, 1) \star (\xi, p)(\pi, q) \in \bot \Rightarrow (\xi, p)(k_n^*, q)(\pi, q) \in \bot \):

Suppose that \( (\xi \star k_n^*, p q) \in \bot \); we must show:

\( (cc^* \star \xi \star \eta, p q) \in \bot \) i.e. \( cc^* \star \xi \star \eta \in \bot \) for \( (p q \prec n) = 1 \). Now, we have:

\( cc^* \star \xi \star \eta \in \bot \) by hypothesis.
\[ (k^* \pi, p) \ast (\xi, q) \ast (\varnothing, r) \in \mathcal{L} \Rightarrow (\xi, q) \ast (\pi, p) \in \mathcal{L} \:
\]

Suppose that \((\xi \ast (\pi, p), q) \in \mathcal{L}\); we must show:

\[ (k_n^* \pi \ast \varnothing, pqr) \in \mathcal{L} \quad \text{i.e.} \quad k_n^* \pi \ast \varnothing \ast (\varnothing, 0) \in \mathcal{L} \quad \text{for} \quad (pqr \vartriangleleft n) = 1. \]

Now, we have:

\[ k_n^* \pi \ast n \ast \varnothing \vartriangleright (\xi \ast n \ast \pi) \quad \text{which is in} \quad \mathcal{L} \quad \text{by hypothesis.} \]

For each closed c-term \(\tau\) (built with the elementary combinators and the application), we define \(\tau^*\) by recurrence, as follows:

if \(\tau\) is an elementary combinator, \(\tau^*\) is already defined; we set \((tu)^* = C\tau^* u^*\).

In the algebra \(B\), the value of the combinator \(\tau\) is \(\tau_B = (\tau^* \pi, 1)\).

In particular, the integer \(n\) of the algebra \(B\) is \(n_B = (n^*, 1)\).

We have \(0_B = (0^*, 1) = (K^*, 1)(\pi^*, 1)\); therefore:

\[ 0^* = CK^*1^*. \]

We have \((n + 1)_B = ((n + 1)^*, 1) = (\sigma^*, 1)(n^*, 1)\); therefore:

\[ (n + 1)^* = C\sigma^* n^*. \]

Thus, we have, for every \(n \in \mathbb{N}\):

\[ n^* = (C\sigma^*)^n0^*. \]

We define the proof-like terms of the algebra \(B\) as the terms of the form \((\theta, 1)\) where \(\theta\) is a proof-like term of the algebra \(A\). The condition of coherence for \(B\) is therefore:

If \(\theta\) is a proof-like term of \(A\), there exist \(n \in \mathbb{N}\) and \(\pi \in \Pi\) such that \(\theta \ast n \ast \pi \notin \mathcal{L}\).

If \(A\) is coherent, then so is \(B\): indeed, if \(\theta\) is a proof-like term of \(A\), then so is \(\theta_B\); this gives a stack \(\pi\) such that \(\theta_B \ast \pi \notin \mathcal{L}\).

**Notations.**

The realizability models associated with the algebras \(A\) and \(B\) are denoted respectively by \(\mathcal{N}_A\) and \(\mathcal{N}_B\).

The truth value of a formula \(F\) in the realizability model \(\mathcal{N}_B\) will be denoted by \(\|F\|_B\) or also \(\|\|F\|\).

We write \((\xi, p) \models_B F\) or \((\xi, p) \models F\) to say that \((\xi, p)\) realizes the formula \(F\) in the realizability model \(\mathcal{N}_B\).

### 3.2 The collapsing function

We now define \(G \in \mathcal{M}\) in the following way:

\[ G = \{(m, \alpha), (\pi, p) \mid m \in \mathbb{N}, \alpha \in \kappa, \pi \in \Pi, p \in P \setminus \{0\}, p(m) \text{ is defined and } p(m) = a\}. \]

**Theorem 35.**

The formula \((\xi, p) \models_B G\) is a surjection from \(\mathbb{N}\) onto \(\downarrow \kappa\) is realized in the model \(\mathcal{N}_B\).

More precisely, we have:

i) \((\theta_0, 1) \mid | |- \forall x \forall y \forall y' ((x, y) \varepsilon G, y \neq y' \rightarrow (x, y') \varepsilon G) \quad \text{with} \quad \theta_0 = \lambda n \lambda x \lambda x(x)n; \]

ii) \((\theta_1, 1) \mid | |- \forall x \forall y [\forall x \forall y \forall y' ((x, y) \varepsilon G, \downarrow) \mid | |- \downarrow] \quad \text{with} \quad \theta_1 = \lambda n \lambda x (((n)(\mathcal{C} \sigma^*)(\mathcal{C} x)0^*)\sigma)n, \]

and \(\sigma = BW (B)B\) (successor).

i) Let \(m \in \mathbb{N}, \alpha, \alpha' \in \kappa, (\pi, p) \in \|(m, \alpha) \varepsilon G\|, (\pi', p') \in \|(m, \alpha') \varepsilon G\|\) and \((\xi, q) \models_B - \alpha \neq \alpha'\).

Thus, we have \(m \in \text{dom}(p), m \in \text{dom}(p'), p(m) = a\) and \(p'(m) = a'\).

By lemma 7, we can replace the formula \((m, \alpha) \varepsilon G\), which is \((- (m, \alpha) \varepsilon G)\), with the set of terms \(\sim (m, \alpha) \varepsilon G\), which is \(\{k_{(x,p)}; (\pi, p) \in \|(m, \alpha) \varepsilon G\|\}\).

Therefore, we have to show that:

\[ (\theta_0, 1) \ast k_{(x,p)} \ast (\xi, q) \ast (\pi', p') \in \mathcal{L} \quad \text{that is} \quad (\theta_0 \ast k_{n^*} \ast \xi \ast \pi^*, pp'q) \in \mathcal{L}. \]
This is obvious if \( pp'q = 0 \). Otherwise, \( p \) and \( p' \) are compatible, thus \( \alpha = \alpha' \).

Let \( n \) be such that \((pp'q < n) = 1\); we must show that \( \theta_0 \ast n \ast k_p \ast \xi \ast \pi' \in \mathbb{N} \) i.e. \( \xi \ast n \ast \pi' \in \mathbb{N} \).

Now, we have \((\xi, q) \models \bot \) by hypothesis on \((\xi, q)\), thus \((\xi, q) \ast (\pi', 1) \in \mathbb{N} \).

Since \((q \sim n) = 1\), it follows that \( \xi \ast n \ast \pi' \in \mathbb{N} \).

ii) Let us first show that \( \theta_1 \ast n \ast \eta \ast \omega \Rightarrow \eta \ast n \ast 1 \ast n^* \ast \omega \) for each \( n \in \mathbb{N}, \eta \in \Lambda \) and \( \omega \in \Pi \).

We have \( \theta_1 \ast n \ast \eta \ast \omega \Rightarrow n \ast (\text{CB})(\ldots) \ast \eta \ast 0^* \ast n^* \ast n \ast 1 \ast \omega \).

By lemma 15(ii), in which we set \( \zeta = \xi = \eta = \sigma = 0^* \), \( \zeta = 0 \) and \( \pi = n \ast 1 \ast \omega \), we obtain: \( \theta_1 \ast n \ast \eta \ast \omega \Rightarrow \eta \ast n \ast 1 \ast n^* \ast \omega \) (since \( n^* = (\text{CB})^0 \ast \omega \)).

We prove now that \((\theta_1, 1) \models \forall x \phi([x, y] \ast \mathcal{G}) \Rightarrow \bot \).

Let \( \alpha \in \kappa, (\eta, p_0) \models \forall x \phi([x, \alpha] \ast \mathcal{G}) \) and \((\omega, q_0) \in \Pi \times P \);

we show that \((\theta_1, 1) \ast (\eta, p_0) \ast (\omega, q_0) \in \mathbb{N} \).

This is trivial if \( p_0q_0 = 0 \); otherwise, let \( n \in \mathbb{N} \) be such that \((p_0q_0 < n) = 1 \).

We must show that \( \theta_1 \ast n \ast \eta \ast \omega \in \mathbb{N} \), that is \( \eta \ast n \ast 1 \ast n^* \ast \omega \in \mathbb{N} \).

But we have \((\eta, p_0) \models ([n^*, 1]) \Rightarrow (n, \alpha) \ast \mathcal{G} \) by hypothesis on \( \eta \).

Since \((p_0q_0 < n) = 1\), we can define \( q \in P \) with domain \( n + 1 \) such that \( q \geq p_0q_0 \) and \( q(n) = \alpha \).

Then, we have \((\omega, q) \in [(n, \alpha) \ast \mathcal{G}] \) by definition of \( \mathcal{G} \).

We have thus \((\eta, p_0) \ast (n^*, 1) \ast (\omega, q) \in \mathbb{N} \) that is \((\eta \ast n^* \ast \omega, p_0q) \in \mathbb{N} \).

But we have \( p_0q = q \), and therefore \((\eta \ast n^* \ast \omega, q) \in \mathbb{N} \).

Since \((q \sim n + 1) = 1\), it follows that \( \eta \ast n + 1 \ast n^* \ast \omega \in \mathbb{N} \).

Q.E.D.

**Corollary 36.** \( \mathcal{N}_{\mathcal{G}} \) realizes the non extensional axiom of choice and thus also DC.

Indeed, by theorem 35, the model \( \mathcal{N}_{\mathcal{G}} \) realizes the formula: (\( \mathfrak{k} \) is countable).

But we have \( \kappa = \text{card}(\Lambda \cup \Pi \cup \mathbb{N}) \), since \( \kappa \geq \text{card}(\Lambda \cup \Pi \cup \mathbb{N}) \) and \( \kappa = \text{card}(P) \).

Therefore \( \mathcal{N}_{\mathcal{G}} \) realizes NEAC, by theorem 31.

Q.E.D.

**Remark.** Intuitively, the model \( \mathcal{N}_{\mathcal{G}} \) is an extension of the model \( \mathcal{N}_{\mathcal{D}} \) obtained by forcing, by collapsing \( \mathfrak{k} \). We cannot apply directly the usual theory of forcing, because \( \mathfrak{k} \) is not defined in ZF.

### 3.3 Elementary formulas

Elementary formulas are defined as follows, where \( t, u \) are \( \ell \)-terms, i.e. terms built with variables, individuals, and function symbols defined in \( \mathcal{M} \):

- \( \top, \bot \) are elementary formulas;
- if \( U \) is an elementary formula, then \( t = u \rightarrow U \) and \( \forall x U \) are too;
- if \( U, V \) are elementary formulas, then \( U \rightarrow V \) too;
- if \( U \) is an elementary formula, then \( \forall n \int U \) too.

**Remark.** \( t \neq u \) is an elementary formula, and also \( t \in \mathfrak{k}U \) (which can be written \( f(t, u) \neq 1 \)) where \( f \) is the function symbol defined in \( \mathcal{M} \) by: \( f(a, b) = 1 \) iff \( a \in b \).

If \( U \) is an elementary formula, then \( \forall x \mathfrak{k}U \) too; indeed, it is written \( \forall x (f(x, t) = 1 \rightarrow U) \).

For each elementary formula \( U \), we define two formulas \( U_p \) and \( U^P \), with one additional free variable \( p \), by the conditions below.

Condition 1 defines \( U_p \) by means of \( U_p ; \) conditions 2 to 5 define \( U_p \) by recurrence:
1. \( \forall p \forall q^P \forall n^{\text{int}}((pq \ll n) = 1 \rightarrow U_q) \);
2. \( \bot_p \equiv \bot \) and \( T_p \equiv T \);
3. \((t = u \leftarrow U)_p \equiv (t = u \leftarrow U_p)\); \((\forall x U[x])_p \equiv \forall x U_p[x]\);
4. \((U \rightarrow V)_p \equiv \forall q^P \forall r^P (p \equiv qr \leftarrow (U^q \rightarrow V_r))\);
5. \((\forall n^{\text{int}} U[n])_p \equiv \forall n^{\text{int}}((n^*_\pi) \rightarrow U_p[n]), \) in other words: 
\[ \| (\forall n^{\text{int}} U[n])_p \| = \{ n^*_\pi ; n \in \mathbb{N}, \pi \in \| U_p[n] \| \}. \]

With the help of these formulas \( U_p, U^P \), we can interpret realizability in the algebra \( \mathcal{B} \) in terms of realizability in the algebra \( \mathcal{A} \), at least for elementary formulas, as shown in the following lemma 37.

**Lemma 37.** For each closed elementary formula \( U \), we have:
\( (\pi, p) \in \| U \| \equiv \pi \in \| U_p \| ; (\xi, p) \equiv U \models \xi \models U^P. \)

Proof by recurrence on the length of the formula \( U \).

1. We have \( (\xi, p) \models U \models (\xi, p) \star (\pi, q) \in \perp \) for \( (\pi, q) \in \| U \| \), that is:
\( (\xi \star \pi, p q) \in \perp \) for every \( \pi \in \| U_q \| \), by the recurrence hypothesis, or also:
\( (\forall q \in P)((\forall \pi \in \| U_q \|)(\forall n \in \mathbb{N})((pq \ll n) = 1 \Rightarrow \xi \star n \pi \in \perp) \) which is equivalent to:
\( \xi \models \forall q^P \forall n^{\text{int}}((pq \ll n) = 1 \rightarrow U_q) \) that is \( \xi \models U^P. \)

2 and 3. Obvious.

4. Any element of \( \| U \rightarrow V \| \) has the form \( (\xi, q) \cdot (\pi, r) \), i.e. \( (\xi \cdot \pi, p) \), with \( p = q r, (\xi, q) \models U \) and \( (\pi, r) \in \| V \| \); by the recurrence hypothesis, this is equivalent to \( \xi \cdot \pi \in \| U^q \rightarrow V_r \| . \)

5. We have \( \| \forall n^{\text{int}} U[n] \| = \| \forall n^{\text{int}}((n^*, 1) \rightarrow U[n]) \| \)
\( = \{ (n^*_\pi, 1) ; n \in \mathbb{N}, (\pi, p) \in \| U[n] \| \} = \{ (n^*_\pi, p) ; n \in \mathbb{N}, (\pi, p) \in \| U[n] \| \}. \)

Thus, by the recurrence hypothesis, it is \( \{ (n^*_\pi, p) ; n \in \mathbb{N}, \pi \in \| U_p[n] \| \}. \)

Q.E.D.

**Lemma 38.**
For each elementary formula \( U \), there exist two proof-like terms \( \theta^0_U, \theta^1_U \), such that:

i) \( \theta^0_U \models \forall p^P \forall n^{\text{int}}((p \ll n) = 1 \rightarrow (U \rightarrow U_p)) \);

ii) \( \theta^1_U \models \forall p^P \forall n^{\text{int}}((p \ll n) = 1 \rightarrow (U_p \rightarrow U)) \);

iii) \( \tau^0_U \models \forall p^P \forall n^{\text{int}}((p \ll n) = 1 \rightarrow (U \rightarrow U^P)) \);

iv) \( \tau^1_U \models \forall p^P \forall n^{\text{int}}((p \ll n) = 1 \rightarrow (U^P \rightarrow U)) \);

with \( \tau^0_U = \lambda n \lambda x \lambda m(\theta^0_U)mx \) and \( \tau^1_U = \lambda n \lambda x(\theta^1_U)(x)n \).

We first show (iii) and (iv) from (i) and (ii).

(i) \( \Rightarrow \) (iii)
Let \( p \in P \) and \( n \in \mathbb{N} \) be such that \( (p \ll n) = 1 \); let \( \xi \models U \) and \( \pi \in \| U^P \| \). We have to show:
\( \lambda n \lambda x \lambda m(\theta^0_U)mx \star n \cdot \xi \cdot \pi \in \perp \).

Now, by the definition (1) of \( U^P \), there exist \( q \in P, m \in \mathbb{N} \) and \( \omega \in \| U_q \| \) such that \( (pq \ll m) = 1 \) and \( \pi = m \cdot \omega \). Therefore, we have \( (q \ll m) = 1 \) and, by (i):
\( \theta^0_U \star m \cdot \xi \cdot \omega \in \perp \), hence \( \lambda n \lambda x \lambda m(\theta^0_U)mx \star n \cdot \xi \cdot m \cdot \omega \in \perp \).

(ii) \( \Rightarrow \) (iv)
Let \( p \in P, n \in \mathbb{N}, \xi \in \Lambda \) and \( \pi \in \| U \| \) such that \( (p \ll n) = 1 \) and \( \xi \models U^P \).

We have to show:
\( \lambda n \lambda x(\theta^1_U)(x)n \star n \cdot \xi \cdot \pi \in \perp \) i.e. \( \theta^1_U \star n \cdot \xi \cdot \pi \in \perp \).
But, by the definition (1) of $U^p$, in which we set $q = p$, we have $\xi_n \vdash U_p$; therefore, the desired result follows from (ii).

We now show (i) and (ii) by recurrence on the length of $U$.

• If $U$ is $\bot$ or $\top$, we take $\theta_U^0 = \theta_U^1 = \lambda n \lambda x x$.

• If $U \equiv (t = u \rightsquigarrow V)$ or $U \equiv \forall x V$, then $\theta_U^0 = \theta_V^0$ and $\theta_U^1 = \theta_V^1$ by (3).

• If $U \equiv V \rightarrow W$, let $q, r \in \mathbb{N}$ and $p = qr$; let $n \in \mathbb{N}$ such that $(p < n) = 1$. We have:
  
  $\preceq \frac{r^0}{n} \vdash V \rightarrow V^q$; $\preceq \frac{r^0}{n} \vdash V^q \rightarrow V$; $\preceq \frac{r^0}{n} \vdash W \rightarrow W_r$; $\preceq \frac{r^0}{n} \vdash W_r \rightarrow W$.

Let $\xi \vdash V \rightarrow W$; then, by the recurrence hypothesis, we have:

$\preceq \frac{r^0}{n} \circ \xi \vdash V \rightarrow W_r$ and $\preceq \frac{r^0}{n} \circ \xi (r^1_n) \vdash V^q \rightarrow W_r$.

Thus, by (4), we obtain $\theta_U^0 = \lambda n \lambda x \lambda y (\theta_W^0 n (x) (r^1_n) y)$.

Now, let $\xi \vdash V^q \rightarrow W_r$; then, by the recurrence hypothesis, we have:

$\preceq \frac{r^1_n}{n} \circ \xi \vdash V^q \rightarrow W$ and $\preceq \frac{r^1_n}{n} \circ \xi (r^0_n) \vdash V \rightarrow W$.

Thus, by (4), we obtain $\theta_U^1 = \lambda n \lambda x \lambda y (\theta_W^1 n (x) (r^0_n) y)$.

• If $U \equiv \forall m \int V[m]$, we first prove:

**Lemma 39.**

There exist two proof-like terms $T_0, T_1$ such that, for every closed formula $F$ of $ZF_e$:

i) $T_0 \vdash \forall n (\forall^{n^2} (\forall^m F \rightarrow (n \rightarrow F))$.

ii) $T_1 \vdash \forall n (\forall^{n^2} (\forall^m F \rightarrow (\forall^m F))$.

iii) For every elementary formula $V[n]$, we have:

$T_0 \vdash (\forall n \int V[n]) \rightarrow (\forall n \int V[n])$ and $T_1 \vdash (\forall n \int V[n]) \rightarrow (\forall n \int V[n])$.

i) We apply lemma 15(ii) to the realizability algebra $A$, with:

$\preceq \frac{\xi}{\sigma}, O = 0, \phi = C \sigma^* \cdot \xi \preceq \frac{\sigma \star \pi}{\pi}$. For every $n \in \mathbb{N}, \xi \in \Lambda$ and $\pi \in \Pi$, we obtain:

$\preceq \frac{n \star (CB)(C) \sigma^* \cdot \xi \star (\sigma \star \pi)}{\sigma \star \pi}$, since $n^* = (C \sigma^*)^0 n^\star$.

Therefore, if we set $T_0 = \lambda f \lambda n ((n)(CB)(C) \sigma^*) f^0$, we have $T_0 \star \xi \star n \star \pi \Rightarrow \xi \star n^* \star \pi$.

Thus, we have $T_0 \vdash \forall n (\forall^m F \rightarrow (n \rightarrow F))$.

ii) We apply now lemma 15(iii) to the realizability algebra $B$, with:

$\preceq \frac{\xi}{\sigma}, O = 0, \phi = (C \Sigma, 1) \alpha = (\Omega, 1)$ and $\Omega = \lambda d \lambda f \lambda a a$; $\Sigma = \lambda n \lambda d \lambda f \lambda a (n(d(f)(f)a)$.

Since $\preceq \frac{\sigma_\mathcal{B}}{\mathcal{B}, 0} = (n^*, 1)$, we get, by setting $\Sigma_2 = (C)^2 \Sigma$:

$\preceq \frac{(n^*, 1) \star (C \Sigma, 1) \cdot (\Omega, 1) \cdot (\omega, 1)}{(\Sigma_2)^0 \Omega, 1 \star (\omega, 1)}$ because $(C \Sigma, 1)^0 (\Omega, 1) = (\Sigma_2)^0 \Omega, 1$.

We write this as:

$\preceq \frac{(n^* \star C \Sigma \cdot \Omega \cdot \omega, 1)}{(\Sigma_2)^0 \Omega, 1 \star (\omega, 1)}$.

It follows that $n^* \star 0 \cdot C \Sigma \cdot \Omega \cdot \omega \Rightarrow (\Sigma_2)^0 \Omega \cdot d \cdot \omega$ for some $d \in \mathbb{N}$.

Let us take $\omega = CB \sigma_\mathcal{B} \cdot \xi \cdot 0 \cdot \pi$.

Now, we apply lemma 16(ii), with $\phi = \sigma$ and $\alpha = 0$ (note that $\Sigma_2 = (C)^2 \Sigma$ satisfies the hypothesis of lemma 16). We obtain $(\Sigma_2)^0 \Omega \cdot d \cdot CB \sigma_\mathcal{B} \cdot \xi \cdot 0 \cdot \pi \Rightarrow \xi \star (\sigma)^0 \star \pi$ and therefore:

$\preceq \frac{n^* \star 0 \cdot C \Sigma \cdot CB \sigma_\mathcal{B} \cdot \xi \cdot 0 \cdot \pi \Rightarrow \xi \star n \star \pi}{n^* \star 0 \cdot C \Sigma \cdot CB \sigma_\mathcal{B} \cdot \xi \cdot 0 \cdot \pi \Rightarrow \xi \star n \star \pi}$.

Finally, if we set $T_1 = \lambda f \lambda n ((n)(CB)(C) \Sigma \Omega) (\Sigma \Omega) f^0$, we have:

$T_1 \star \xi \star n \star \pi \Rightarrow \xi \star n \star \pi$ and therefore $T_1 \vdash (\forall n (\forall^m F \rightarrow (\forall^m F))$.

iii) This follows immediately from (i) and (ii), by definition of $(\forall n \int V[n])$.

Q.E.D.
We can now finish the proof of lemma 38, considering the last case which is :
• $U \equiv \forall m^{\text{int}}V[m]$.

We show that $\theta^0_\lambda = \lambda n \lambda x(T_1) \lambda m(\theta^0_\lambda n)(x)m$.

By the recurrence hypothesis, we have $\theta^0_\lambda \parallel \forall p^2 \forall n \text{int}((p \ll n) = 1 \leftrightarrow (V[m] \rightarrow V_p[m]))$.

Let $p \in P$, $n \in \mathbb{N}$, $\xi \in \Lambda$ be such that $(p \ll n) = 1$ and $\xi \parallel \forall m^{\text{int}}V[m]$.

Then, for every $m \in \mathbb{N}$, we have $\xi m \parallel V[m]$ ; thus $(\theta^0_\lambda n)(\xi) m \parallel V_p[m]$ and therefore :

$\lambda m(\theta^0_\lambda n)(\xi) m \parallel \forall m^{\text{int}}V_p[m]$.

By lemma 39(iii), we get :

$(T_1) \lambda m(\theta^0_\lambda n)(\xi) m \parallel (\forall m^{\text{int}}V[m])_p$ and therefore :

$\lambda n \lambda x(T_1) \lambda m(\theta^0_\lambda n)(x)m \parallel \forall p^2 \forall n \text{int}((p \ll n) = 1 \leftrightarrow (V[m] \rightarrow (\forall m^{\text{int}}V[m]))_p)$.

We show now that $\theta^1_\lambda = \lambda n \lambda x \lambda m(\theta^1_\lambda n)(T_0)xm$.

By the recurrence hypothesis, we have $\theta^1_\lambda \parallel \forall p^2 \forall n \text{int}((p \ll n) = 1 \leftrightarrow (V_p[m] \rightarrow V[m]))$ ;

Let $p \in P$, $n \in \mathbb{N}$, $\xi \in \Lambda$ be such that $(p \ll n) = 1$ and $\xi \parallel (\forall m^{\text{int}}V[m])_p$.

By lemma 39(iii), we have $T_0 \xi \parallel \forall m^{\text{int}}V_p[m]$, thus $T_0 \xi m \parallel V_p[m]$.

Therefore $(\theta^1_\lambda n)(T_0)\xi m \parallel V[m]$, and $\lambda m(\theta^1_\lambda n)(T_0)\xi m \parallel \forall m^{\text{int}}V[m]$, hence the result.

Q.E.D.

**Theorem 40.**

*The same closed elementary formulas, with parameters in $\mathcal{M}$, are realized in the models $\mathcal{N}_d$ and $\mathcal{N}_\beta$.***

Let $U$ be a closed elementary formula, which is realized in $\mathcal{N}_d$ and let $\theta$ be a proof-like term such that $\theta \parallel U$. Then, we have $(\tau^0_U \theta) \parallel U^p$ for $(p \ll n) = 1$, by lemma 38(iii) ; therefore, setting $p = \phi = 1$, we have $(\tau^0_\lambda \theta, 1) \parallel U$ by lemma 37.

Therefore, the formula $U$ is also realized in the model $\mathcal{N}_\beta$.

Conversely, if $(\theta, 1) \parallel U$ with $\theta \in \text{QP}$, we have $\theta \parallel U^1$, by lemma 37. Thus $\tau^1_U \theta \parallel U$ by lemma 38(iv).

Q.E.D.

**Remark.** For instance :

• If the Boolean algebra $\mathcal{J}$ has four $\varepsilon$-elements or if it is atomless, in the model $\mathcal{N}_d$, the same goes for the model $\mathcal{N}_\beta$.

• Arithmetical formulas are elementary. Therefore, by theorem 40, the models $\mathcal{N}_d$ and $\mathcal{N}_\beta$ realize the same arithmetical formulas. In fact, this was already known, because they are the same as the arithmetical formulas which are true in $\mathcal{M}$ [15, 16].

### 3.4 Arithmetical formulas and dependent choice

In this section, we obtain, by means of the previous results, a technique to transform into a program, a given proof, in $\text{ZF} + \text{DC}$, of an arithmetical formula $F$.

We notice that this program is a closed $c$-term, written with the elementary combinators $B, C, I, K, W, cc$ without any other instruction.

Thus, let us consider a proof of $\text{ZF}_\varepsilon \vdash \text{NEAC} \rightarrow F$ (NEAC is the *non extensional axiom of choice*, see section 2.3).

It gives us a closed $c$-term $\Phi_0$ such that $\Phi_0 \parallel \text{NEAC} \rightarrow F$, in every realizability algebra.
We now describe a rewriting on closed c-terms, which will transform $\Phi_0$ into a closed c-term $\Phi$ such that $\Phi \vdash F$ in every realizability algebra $\mathcal{A}$.

By theorem 31, we have $\Phi_1 \vdash (\mathcal{K} \text{ is countable}) \rightarrow F$ with $\Phi_1 = \lambda x(\Phi_0)(H)x$.

We apply this result in the algebra $\mathcal{B}$, which gives:

$(\Phi_1^*, 1) \parallel (\mathcal{K} \text{ is countable}) \rightarrow F$.

Now, theorem 35 gives a closed c-term $\Delta$ such that $(\Delta, 1) \parallel (\mathcal{K} \text{ is countable})$.

Since $F$ is an arithmetical formula, it is an elementary formula. Therefore, by lemma 37, we have $\Psi \parallel F^1$. Now, by lemma 38(iv), we have:

$\tau_1 \vdash \forall p \mathcal{P} \forall n \mathit{int}((p \ll n) = 1 \rightarrow (F^p \rightarrow F))$.

We set $p = 1$ and $n = 0$, and we obtain $\tau_1 \vdash F^1 \rightarrow F$.

Finally, by setting $\Phi = (\tau_1 \Psi)^0$, we have $\Phi \parallel F$.

### 3.5 A relative consistency result

In [18], we have defined a countable realizability algebra $\mathcal{A}$ such that the characteristic Boolean algebra $\mathcal{G}_\mathcal{A}$ of the model $\mathcal{N}_\mathcal{A}$ is atomless (in this example, we have $\kappa = \mathbb{N}$).

If we apply the technique of section 3, in order to collapse $\mathcal{K}$, we obtain a realizability algebra $\mathcal{B}$ and a model $\mathcal{N}_\mathcal{B}$, the characteristic Boolean algebra of which is also atomless. Indeed, the property : ($\mathcal{G}$ is atomless) is expressed by an elementary formula.

But now $\mathcal{G}$ is the countable atomless Boolean algebra (they are all isomorphic). Therefore, by applying theorems 31 and 34, we obtain the relative consistency result (i) announced in the introduction.

**Remark.** We note that this method applies to every realizability algebra such that we have : $\parallel (\mathcal{G} \text{ is an atomless Boolean algebra})$.

### 4 A two threads model ($\mathcal{G}$ with four elements)

In this section, we suppose that $\mathcal{A}$ is a standard realizability algebra [18].

This means, by definition, that the terms and the stacks are finite sequences, built with:

- the alphabet $B, C, I, K, W, cc, k, \ast, (, ), [ , ]$
- a countable set of term constants (also called instructions),
- a countable set of stack constants

and that they are defined by the following rules:

- $B, C, I, K, W, cc$ and all the term constants are terms;
- if $t, u$ are terms, the sequence $(t)u$ is a term;
- if $\pi$ is a stack, the sequence $k[\pi]$ is a term (denoted by $k_\pi$);
- each stack constant is a stack;
- if $t$ is a term and $\pi$ is a stack, then $t \ast \pi$ is a stack.

If $t$ is a term and $\pi$ is a stack, then the ordered pair $(t, \pi)$ is a process, denoted by $t \ast \pi$.

A proof-like term of $\mathcal{A}$ is a term which does not contain the symbol $k$; or, which is the same, a term which does not contain any stack constant.

We now build a realizability model in which $\mathcal{G}$ has exactly 4 elements.
We suppose that there are exactly two stack constants $\pi^0$, $\pi^1$ and one term constant $d$. For $i \in \{0, 1\}$, let $\Lambda^i$ (resp. $\Pi^i$) be the set of terms (resp. stacks) which contain the only stack constant $\pi^i$. For $i, j \in \{0, 1\}$, define $\bot^i_j$ as the least set $P \subseteq \Lambda^i \star \Pi^i$ of processes such that:

1. $d \star j \cdot \pi \in P$ for every $\pi \in \Pi^i$.
2. $\xi \star \pi \in \Lambda^i \star \Pi^i$, $\xi' \star \pi' \in P$, $\xi \star \pi \triangleright \xi' \star \pi' \Rightarrow \xi \star \pi \in P$
3. If at least two out of three processes $\xi \star \pi, \eta \star \pi, \zeta \star \pi$ are in $P$, then $d \star 2 \cdot \xi \cdot \eta \cdot \zeta \cdot \pi \in P$.

**Remarks.**

The preorder $\triangleright$ on $\Lambda \star \Pi$ was defined at the beginning of section 1. We express condition 2 by saying that $P$ is saturated in $\Lambda^i \star \Pi^i$.

Following this definition of $\triangleright$, the constant $d$ is a halting instruction. Indeed, we have:

$$d \star \pi \triangleright \xi \star \omega \iff \xi \star \omega = d \star \pi.$$ 

We define $\bot$ by:

$$\Lambda \star \Pi \setminus \bot = (\Lambda^0 \star \Pi^0 \setminus \bot^0_0) \cup (\Lambda^1 \star \Pi^1 \setminus \bot^1_1).$$

In other words, a process is in $\bot$ if and only if either it is in $\bot^0_0 \cup \bot^1_1$ or it contains both stack constants $\pi^0, \pi^1$.

**Lemma 41.** If $\xi \star \pi \in \bot^i_j$ and $\xi \star \pi \triangleright \xi' \star \pi'$ then $\xi' \star \pi' \in \bot^i_j$ (closure by reduction).

Suppose that $\xi_0 \star \pi_0 > \xi'_0 \star \pi'_0$, $\xi_0 \star \pi_0 \in \bot^i_j$ and $\xi'_0 \star \pi'_0 \notin \bot^i_j$. We may suppose that:

$$(*) \quad \xi_0 \star \pi_0 > \xi'_0 \star \pi'_0 \text{ in exactly one step of reduction.}$$

Let us show that $\bot^i_j \setminus \{\xi_0 \star \pi_0\}$ has properties 1, 2, 3 defining $\bot^i_j$, which will contradict the definition of $\bot^i_j$:

1. If $\xi_0 \star \pi_0 = d \star j \cdot \pi$, with $\pi \in \Pi^i$, then $d \star j \cdot \pi \triangleright \xi'_0 \star \pi'_0$, thus $\xi'_0 \star \pi'_0 = d \star j \cdot \pi$. Therefore $\xi'_0 \star \pi'_0 \notin \bot^i_j$, which is false.
2. Suppose $\xi \star \pi \in \Lambda^i \star \Pi^i$, $\xi \star \pi \triangleright \xi' \star \pi' \in \bot^i_j$, $\xi' \star \pi' \neq \xi_0 \star \pi_0$. Then $\xi \star \pi \in \bot^i_j$, by (2). If $\xi \star \pi = \xi_0 \star \pi_0$, then $\xi_0 \star \pi_0 > \xi'_0 \star \pi'$; since $\xi' \star \pi' \neq \xi_0 \star \pi_0$, it follows from (*) that $\xi'_0 \star \pi'_0 > \xi' \star \pi'$ and therefore $\xi'_0 \star \pi'_0 \in \bot^i_j$, which is false.
3. Suppose that two out of the processes $\xi \star \pi, \eta \star \pi, \zeta \star \pi$ are in $\bot^i_j \setminus \{\xi_0 \star \pi_0\}$, but $d \star 2 \cdot \xi \cdot \eta \cdot \zeta \cdot \pi$ is not. From (3), it follows that $d \star 2 \cdot \xi \cdot \eta \cdot \zeta \cdot \pi = \xi_0 \star \pi_0$. Thus, $d \star 2 \cdot \xi \cdot \eta \cdot \zeta \cdot \pi > \xi'_0 \star \pi'_0$, and therefore $\xi'_0 \star \pi'_0 = d \star 2 \cdot \xi \cdot \eta \cdot \zeta \cdot \pi$. Therefore $\xi'_0 \star \pi'_0 \in \bot^i_j$, which is false.

Q.E.D.

**Lemma 42.** $\bot^0_0 \cap \bot^1_1 = \emptyset$.

We prove that $(\Lambda^i \star \Pi^i \setminus \bot^i_1) \cup \bot^i_1$ by showing that $\Lambda^i \star \Pi^i \setminus \bot^i_1$ has properties 1, 2, 3 which define $\bot^i_0$.

1. $d \star 0 \cdot \pi \notin \bot^i_1$ because $\bot^i_1 \setminus \{d \star 0 \cdot \pi\}$ has properties 1, 2, 3 defining $\bot^i_1$.
2. Follows from lemma 41.
3. Suppose $\xi_0 \star \pi_0, \eta_0 \star \pi_0 \in \bot^i_1$; we show that $d \star 2 \cdot \xi_0 \cdot \eta_0 \cdot \xi_0 \cdot \pi_0 \notin \bot^i_1$ by showing that $\bot^i_1 \setminus \{d \star 2 \cdot \xi_0 \cdot \eta_0 \cdot \xi_0 \cdot \pi_0\}$ has properties 1, 2, 3 defining $\bot^i_1$.

1. Clearly, $d \star 1 \cdot \pi' \in (\bot^i_1 \setminus \{d \star 2 \cdot \xi_0 \cdot \eta_0 \cdot \xi_0 \cdot \pi_0\})$ for every $\pi' \in \Pi^i$. 27
2. Suppose that \( \xi \neq \pi \in \Lambda^i \times \Pi^i \), \( \xi \neq \pi > \xi' \neq \pi' \in \mathbb{P}_{i,1} \), \( \xi' \neq \pi' \neq d \neq 2 \xi_0 \cdot \eta_0 \cdot \zeta_0 \cdot \pi_0 \) and that
\[
\xi' \neq \pi \in (\mathbb{P}_{i,1} \setminus (d \neq 2 \xi_0 \cdot \eta_0 \cdot \zeta_0 \cdot \pi_0)).
\]
From (2), it follows that \( \xi \neq \pi = d \neq 2 \xi_0 \cdot \eta_0 \cdot \zeta_0 \cdot \pi_0 \) which contradicts \( \xi \neq \pi > \xi' \neq \pi' \).

3. Suppose that two out of the processes \( \xi \neq \pi, \eta \neq \pi, \zeta \neq \pi \) and \( \pi = \pi_0 \).
It follows from (3) that \( d \neq 2 \xi_0 \cdot \eta_0 \cdot \zeta_0 \cdot \pi_0 \) and \( \pi = \pi_0. \) But this contradicts the hypothesis \( \xi_0 \neq \pi_0, \eta_0 \neq \pi_0 \in \mathbb{P}_{i,1}. \)

Q.E.D.

**Theorem 43.** This realizability algebra is coherent.

Let \( \theta \in \text{QP} \) be such that \( \theta \neq \pi^0 \in \mathbb{P}_{0} \) and \( \theta \neq \pi^1 \in \mathbb{P}_{1} \). Then \( \theta \neq \pi^0 \in \mathbb{P}_{0} \cap \mathbb{P}_{1} \) which contradicts lemma 42.

Q.E.D.

**Lemma 44.** \( d_2 \models (\text{the boolean algebra } \mathcal{A} \text{ has at most four } \varepsilon \text{-elements}). \)

We show that \( d_2 \models \forall x^2 \forall y^2 (x \neq 0, y \neq 1, x \neq y \rightarrow x \land y \neq x). \)

Let \( i, j \in \{0, 1\}, \xi \models i \neq 0, \eta \models j \neq 1, \zeta \models i \neq j \) and \( \pi \models i \neq j \).

Since \( i \neq j \), we have \( i \neq j. \) Thus, there are three possibilities for \( (i, j) : 
\begin{align*}
i = j &= 0; \ i = j = 1; \ i = 0, j = 1.
\end{align*}

In each case, two out of the terms \( \xi, \eta, \zeta \) realize \( \bot. \) Thus, we have \( d \neq 2 \xi_0 \cdot \eta_0 \cdot \zeta_0 \cdot \pi \in \mathbb{P}. \)

Q.E.D.

**Remark.** If \( \pi \in \Pi \setminus (\Pi^0 \cup \Pi^1) \), then \( \xi \neq \pi \in \mathbb{P} \) for every term \( \xi. \) Thus, we can remove these stacks and consider only \( \Pi^0 \cup \Pi^1. \)

We define two individuals in this realizability model:
\[
\gamma_0 = (\{0\} \times \Pi^0) \cup (\{1\} \times \Pi^1) ; \gamma_1 = (\{1\} \times \Pi^0) \cup (\{0\} \times \Pi^1).
\]
Obviously, \( \gamma_0, \gamma_1 \in \mathcal{A} \neq \mathbb{P} \times \Pi. \) Now we have:
\[
\| \forall x^2 (x \neq \gamma_0) \| = \Pi^0 \cup \Pi^1 = \mathbb{P} \text{ and therefore } 1 \models \forall x^2 (x \neq \gamma_0).
\]
\( d_0 \models 0 \neq \gamma_0 \) and \( d_1 \models 1 \neq \gamma_0. \)

It follows that \( \gamma_0, \gamma_1 \) are not \( \varepsilon \)-empty and that every \( \varepsilon \)-element of \( \gamma_0, \gamma_1 \) is not \( \neq 0, 1. \) Therefore:

The Boolean algebra \( \mathcal{A} \) has exactly four \( \varepsilon \)-elements.

We have \( \xi \models \forall x^2 (x \neq \gamma_0, x \neq \gamma_1 \rightarrow \bot) \) for every term \( \xi: \)

Indeed, let \( i, j \in \{0, 1\} ; \) using lemma 7, we replace the formula \( i \neq \gamma_j, \) i.e. \( \neg (i \neq \gamma_j), \) with \( \neg (i \neq \gamma_j) \) which is \( (k_{\pi}; \pi \in \Pi^{i+j}). \) Therefore, we have to check:
\[
\rho_0 \in \Pi^0, \rho_1 \in \Pi^1 \Rightarrow \xi \neq k_{\rho_0} \cdot k_{\rho_1} \cdot \pi \in \mathbb{P} \text{ which is clear.}
\]

In the same way, we get:
\[
\lambda x \lambda y \lambda z \models \forall x \forall y (x \neq \gamma_j, y \neq \gamma_j, x \neq y \rightarrow \bot).
\]

It follows that \( \gamma_0, \gamma_1 \) are singletons and that their \( \varepsilon \)-elements are the two atoms of \( \mathcal{A}. \)

**4.1 \( \mathcal{A} \) has four \( \varepsilon \)-elements and \( \mathcal{A} \) is countable**

We now apply to the algebra \( \mathcal{A} \) the technique expounded in section 3, in order to make \( \mathcal{A} \) countable; this gives a realizability algebra \( \mathcal{B}. \)

In this case, we have \( \kappa = \mathbb{N} \), and therefore \( \kappa^+ = \mathcal{P}(\kappa) = \mathbb{R}. \)
Now, there is an elementary formula which expresses that the Boolean algebra $\mathbb{2}$ has four $\varepsilon$-elements, for instance:  
$\exists x^\mathbb{2}(x \neq 0, x \neq 1) \land \forall x^\mathbb{2} \forall y^\mathbb{2}(x \neq 1, y \neq 1, x \neq y \rightarrow xy = 0)$.  
Therefore, the realizability model $\mathcal{N}_d$ realizes the following two formulas:  
($\mathbb{2}$ has four $\varepsilon$-elements); ($\kappa$ is countable);  
and therefore also NEAC by theorem 31.

Let us denote by $i_0, i_1$ the two atoms of $\mathbb{2}$; thus, we have $i_1 = 1 - i_0$.

We suppose that $\mathcal{M} \models V = L$; thus, there exists on $\kappa_+ = \mathcal{P}(\mathbb{N}) = \mathbb{R}$ a strict well ordering $\prec$ of type $\aleph_1$. This gives a function from $\mathbb{R}^2$ into $\{0, 1\}$, denoted by $(x \prec y)$, which is defined as follows:  
$(x \prec y) = 1 \iff x < y$.

We can extend it to $\mathcal{N}_d$ and $\mathcal{N}_B$, which gives a function from $(\mathbb{R})^2$ into $\mathbb{2}$.

From lemmas 29 and 30, we get:  
For $i = i_0$ or $i_1$, the relation $(x \prec y) = i$ is a strict total ordering on $\mathbb{J}_i \mathbb{R}$ and one of these two relations is a well ordering;  
in order to fix the ideas, we shall suppose that it is for $i = i_0$.

The relation $(x \prec y) = 1$ is a strict order relation on $\mathbb{J}_i \mathbb{R}$, which is well founded.

The application $x \mapsto (i_0x, i_1x)$ from $\mathbb{J}_i \mathbb{R}$ onto $\mathbb{J}_{i_0} \mathbb{R} \times \mathbb{J}_{i_1} \mathbb{R}$ is an isomorphism of strictly ordered sets.

It follows from theorem 26, that each of the sets $\mathbb{J}_{i_0} \mathbb{R}, \mathbb{J}_{i_1} \mathbb{R}$ contains a countable subset.

By corollary 24, there is no surjection from each one of the sets $\mathbb{J}_{i_0} \mathbb{R}, \mathbb{J}_{i_1} \mathbb{R}$ onto the other. Thus, there is no surjection from $\mathbb{N}$ onto $\mathbb{J}_{i_0} \mathbb{R}$ or onto $\mathbb{J}_{i_1} \mathbb{R}$.

Therefore, the well ordering on $\mathbb{J}_{i_0} \mathbb{R}$ has, at least, the order type $\aleph_1$ in $\mathcal{N}_B$.

Now, by theorem 32, every subset of $\mathbb{J}_\mathbb{R}$, which is bounded from above for the ordering $\prec$, is countable; thus, the same goes for the proper initial segments of $\mathbb{J}_{i_0} \mathbb{R}$ and $\mathbb{J}_{i_1} \mathbb{R}$, since these sets are totally ordered and $\mathbb{J}_\mathbb{R}$ is isomorphic to $\mathbb{J}_{i_0} \mathbb{R} \times \mathbb{J}_{i_1} \mathbb{R}$.

It follows that the well ordering on $\mathbb{J}_{i_0} \mathbb{R}$ is at most $\aleph_1$, and therefore exactly $\aleph_1$.

Moreover, there exists, on $\mathbb{J}_{i_1} \mathbb{R}$, a total ordering, every proper initial segment of which is countable.

Then, we can apply theorem 34, to the sets $X_{i_0}, X_{i_1}$ which are the images of $\mathbb{J}_{i_0} \mathbb{R}, \mathbb{J}_{i_1} \mathbb{R}$ by the injection from $\mathbb{J}_\kappa$ into $\mathbb{R}$, which is given by theorem 33. By setting $X = X_{i_1}$, we obtain exactly the result (ii) of relative consistency announced in the introduction.
