# Disjointedness of additive and multiplicative structures

### Theorem (Solymosi - 2009)

For any finite set  $A \subset \mathbb{R}$ ,

$$\max |A \cdot A|, |A + A| \gg |A|^{4/3 - o(1)}$$
.

### Conjecture (Chowla)

Let  $\lambda(n) = (-1)^k$ , where k is the number of prime factors of n. Then for all  $a_1 < a_2 < \ldots < a_m$ 

$$\lim_{N\to\infty}\frac{1}{N}\sum_{n\leq N}\lambda(n+a_1)\cdot\lambda(n+a_2)\cdots\lambda(n+a_m)=0.$$

# Sarnak Conjecture

The Möbius function is defined by

$$\mu(n) = \left\{ \begin{array}{ll} (-1)^k & \text{if $n$ is squarefree and} \\ k & \text{is the number of prime factors} \\ 0 & \text{otherwise.} \end{array} \right.$$

A dynamical system is said to be determinist, if its topological entropy is 0.

### Conjecture (Sarnak - 2010)

For every complex sequence  $u = (u_n)_{n>0}$  that is obtained by a deterministic dynamical system,

$$\lim_{N\to\infty}\frac{1}{N}\sum_{n\leq N}u_n\mu(n)=0.$$

# Multiplicative functions

### Definition (Multiplicative function)

A function  $f : \mathbb{N} \to \mathbb{C}$  is called *(completely) multiplicative* if f(nm) = f(n)f(m) for all n, m that are coprime (for all n, m).

Examples:  $\mu, \lambda$ 

### Definition (Dirichlet character)

We call  $\chi: \mathbb{Z} \to \mathbb{C}$  a Dirichlet character (of modulus m) if

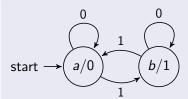

- There exists m > 0 such that  $\chi(n) = \chi(n+m)$  for all n.
- If  $\gcd(n,m) > 1$  then  $\chi(n) = 0$ ; if  $\gcd(n,m) = 1$  then  $\chi(n) \neq 0$ .
- $\circ$   $\chi$  is completely multiplicative.

## Deterministic Finite Automata

### Definition (Automaton - DFA)

$$A = (Q, \Sigma = \{0, \dots, k-1\}, \delta, q_0, \tau)$$

### Example (Thue-Morse sequence)

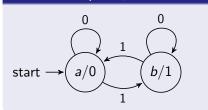

$$n = 22 = (10110)_2, \qquad u(22) = 1$$

$$u = (u(n))_{n>0} = 01101001100101101001011001101001...$$

## Different Points of View I

$$(u(n))_{n>0} = 01101001100101101001011001101001...$$

### Automaton (Computer Science)

### Substitution (Dynamics)

Coding of the fixpoint of a constant-length substitution:

$$a o ab$$
  $a \mapsto 0$ 

$$b o ba$$
  $b \mapsto 1$ 

## Different Points of View II

 $(u(n))_{n\geq 0} = 01101001100101101001011001101001\dots$ 

### Formal Power Series (Algebra)

Algebraicity over  $F_q(X)$ .

$$t(X) := \sum_{n \ge 0} u(n) X^n$$

$$X + (1+X)^2 t(X) + (1+X)^3 t(X)^2 = 0$$

### Finite Kernel

The  $\lambda$ -kernel of a sequence a(n) is defined as

$$\{(a(n\lambda^k+r))_{n\geq 0}: k\geq 0, 0\leq r<\lambda^k\}.$$

a(n) is  $\lambda$ -automatic iff its  $\lambda$ -kernel is finite.

# Being automatic in different bases

### Question

Can a sequence be automatic in multiple bases?

#### Lemma

Let  $\lambda, k \in \mathbb{N}$ . A sequence is  $\lambda$ -automatic if and only if it is  $\lambda^k$ -automatic.

Proof works by considering the kernel.

### Theorem (Cobham - 1972)

If a sequence  $(a(n))_{n\geq 0}$  is both  $\mu$  and  $\lambda$  automatic, where  $\log(\mu)/\log(\lambda) \notin \mathbb{Q}$ . Then  $(a(n))_{n\geq 0}$  is eventually periodic.

# Simple examples and Properties

#### Lemma

Let  $(a(n))_{n\geq 0}$  be eventually periodic. Then it is  $\lambda$ -automatic for every  $\lambda \in \mathbb{N}$ .

Proof: Follows from considering the  $\lambda$ -kernel.

### Lemma

Let  $a_1(n)$ ,  $a_2(n)$  be,  $\lambda$ -automatic sequences, then so is  $(a_1(n) \cdot a_2(n))$ .

Proof: We look at the corresponding  $\lambda$ -kernels:

$$\begin{aligned} \big\{ \big( a_1 \big( n \lambda^k + r \big) \cdot a_2 \big( n \lambda^k + r \big) : k \in \mathbb{N}, 0 \le r < \lambda^k \big\} \\ &\subset \big\{ \big( a_1 \big( n \lambda^k + r \big) : k \in \mathbb{N}, 0 \le r < \lambda^k \big\} \\ &\cdot \big\{ \big( a_2 \big( n \lambda^k + r \big) : k \in \mathbb{N}, 0 \le r < \lambda^k \big\}. \end{aligned}$$

# Disjointedness of automatic and multiplicative sequences

### Theorem (M. - 2017)

Any automatic sequence is orthogonal to the Möbius function. (Also true for the associated dynamical system.) If the automatic sequence is primitive, then we also have a prime number theorem.

### Theorem (Lemańczyk, M. - 2020)

Let a be a primitive automatic sequence. Then it is orthogonal to any bounded, aperiodic, multiplicative function  $u : \mathbb{N} \to \mathbb{C}$ , i.e.

$$\lim_{N\to\infty}\frac{1}{N}\sum_{n\leq N}a(n)u(n)=0.$$

### Naive Question

Why not all bounded multiplicative functions?

Trivial counter-example: periodic sequences (e.g. Dirichlet characters).

Non-trivial counter-example:  $a(n) = (-1)^{\nu_2(n)}$ .

### Definition (aperiodic sequence)

We call a sequence u aperiodic if for all  $k, \ell \in \mathbb{N}$ 

$$\lim_{N\to\infty}\frac{1}{N}\sum_{n\leq N}u(kn+\ell)=0.$$

# Disjointedness of multiplicative sequences and algebraic generating series

### Theorem (Bell, Bruin and Coons - 2012)

Let K be a field of characteristic 0, let  $f: \mathbb{N} \to K$  be a multiplicative function, and its generating series

$$F(z) = \sum_{n \ge 1} f(n)z^n$$
 be algebraic over  $K(z)$ .

Then either f is finitely supported or there is a natural number k and a periodic multiplicative function  $\chi: \mathbb{N} \to K$  such that

$$f(n) = n^k \chi(n)$$
 for all  $n$ .

## BBC-Conjecture

### Conjecture (Bell, Bruin and Coons - 2012)

For any multiplicative automatic sequence  $a: \mathbb{N} \to \mathbb{C}$  there exists an eventually periodic function  $f: \mathbb{N} \to \mathbb{C}$  such that f(p) = a(p) for all primes p.

### Theorem/Corollary (Klurman, Kurlberg; Konieczny - 2019)

The conjecture is true. Moreover, there exists  $h, \lambda$  such that a is  $\lambda$ -automatic and coincides with  $\chi$  on integers that are coprime to  $h\lambda$ , where  $\chi$  is either zero or a Dirichlet character.

- $\chi$  is a Dirichlet character: dense case
- $\chi = 0$ : sparse case.

## Result

### Theorem (Konieczny, Lemańczyk, M. - 2020+)

A sequence  $a: \mathbb{N} \to \mathbb{C}$  is multiplicative and automatic if and only if there exists a prime p such that a is p-automatic and of the form

$$a(n) = f_1(\nu_p(n)) \cdot f_2(n/p^{\nu_p(n)}), \tag{1}$$

where  $f_1$  is eventually periodic and  $f_2$  is multiplicative, eventually periodic and vanishes at all multiples of p.

# Simple example

#### Lemma

Let  $(a(n))_{n\geq 0}$  be multiplicative and p-automatic. Then

$$a(n) = a(p^{\nu_p(n)}) \cdot a(n/p^{\nu_p(n)}),$$

where  $\alpha \mapsto a(p^{\alpha})$  is eventually periodic.

Proof: The first part follows by multiplicativity.

As the *p*-kernel is finite, there exists  $k_1, k_2 \in \mathbb{N}$  such that  $a(np^{k_1}) = a(np^{k_2})$  for all  $n \in \mathbb{N}$ .

Choose  $n = p^{\alpha}$ .

### Corollary

Theorem 1 is true for eventually periodic multiplicative sequences (for every p).

### Lemma

Let  $f_1$  be eventually periodic with  $f_1(0) = 1$ . Then  $a_1(n) = f_1(\nu_p(n))$  is p-automatic and multiplicative.

Proof: We consider again the p-kernel,

$$\{(f_1(\nu_p(np^k+r)))_{n\geq 0}: k\in\mathbb{N}, 0\leq r< p^k\}$$
  
=\{f\_1(\nu\_p(n)+k)\_{n\geq 0}: k\in\mathbb{N}\} \cup \{f\_1(\nu\_p(r))\_{n\geq 0}: r\in\mathbb{N}\}

Multiplicativity: If (m, n) = 1 then either  $p \nmid m$  or  $p \nmid n$ . Thus, we have  $\nu_p(mn) = \max(\nu_p(m), \nu_p(n))$  and  $f_1(mn) = f_1(m)f_1(n)$ .

### Lemma

Let  $f_2$  be multiplicative and eventually periodic. Then  $a_2(n) = f_2(n/p^{\nu_p(n)})$  is *p*-automatic and multiplicative.

Proof: We consider once again the *p*-kernel:

$$\begin{aligned} \{(a_2(np^k + r))_{n \ge 0} : k \in \mathbb{N}, 0 \le r < p^k\} \\ &= \{(a_2(np^k))_{n \ge 0} : k \in \mathbb{N}\} \\ & \cup \{(a_2(np^k + r))_{n \ge 0} : k \in \mathbb{N}, 0 < r < p^k\} \\ &= \{(a_2(n))_{n \ge 0}\} \cup \{(f_2(np^\ell + s))_{n \ge 0} : \ell \in \mathbb{N}, 0 < s < p^\ell\}. \end{aligned}$$

Let (m, n) = 1. Then also  $(m/p^{\nu_p(m)}, n/p^{\nu_p(n)}) = 1$ . Thus,  $a_2$  is also multiplicative.

# Decomposing Dirichlet characters

### Lemma

Let  $\chi$  be a Dirichlet character of modulus  $m=m_1m_2$  where  $(m_1,m_2)=1$ . Then  $\chi=\chi_{m_1}\cdot\chi_{m_2}$ , where  $\chi_{m_i}(n)$  is a Dirichlet character of modulus  $m_i$  and  $\chi_{m_i}(n)=\chi(n_i)$  with

 $n_i \equiv n \mod m_i$  $n_i \equiv 1 \mod m/m_i$ .

### Corollary

Let  $\chi$  be a Dirichlet character of modulus m. Then

$$\chi(n) = \prod_{p|m} \chi_{p^{\nu_p(m)}}(n).$$

## Dense case

Assumption:  $\nu_p(h\lambda) = 1$  for all  $p \mid h\lambda!$ Thus,  $\chi = \prod_{p \mid h\lambda} \chi_p$ .

### Proposition

Let a(n) be a dense multiplicative automatic sequence. Then

$$a(n) = \prod_{p \mid h\lambda} \frac{a(p^{\nu_p(n)})}{\chi(\overline{p})^{\nu_p(n)}} \cdot \chi_p\left(\frac{n}{p^{\nu_p(n)}}\right),$$

where  $\chi(\overline{p}) = \chi_{h\lambda/p}(p)$ .

# Dynamical systems

### Dynamical System (X, T) related to u

$$u = (u_n)_{n \ge 0} \dots$$
 bounded complex sequence

$$T(\mathsf{u}) = (u_{n+1})_{n \geq 0} \dots$$
 shift operator

$$X = \overline{\{T^k(\mathsf{u}) : k \ge 0\}}$$

### Theorem (M., Yassawi; 2019)

Let a be a primitive  $\lambda$ -automatic sequence, which is not periodic. Then the continuous eigenvalues of (X, T) are isomorphic to  $\mathbb{Z}(\lambda) \times \mathbb{Z} / h \mathbb{Z}$ , where h is the height of a.

## Intuition I

$$a(n) = \prod_{\substack{n \mid h \lambda}} \frac{a(p^{\nu_p(n)})}{\chi(\overline{p})^{\nu_p(n)}} \cdot \chi_p\left(\frac{n}{p^{\nu_p(n)}}\right).$$

- The right hand side looks like a product of *p*-automatic sequences, where  $p \mid h\lambda$ .
- Thus we expect the continuous eigenvalues to be  $\approx \mathbb{Z}(h\lambda)$ .
- The continuous eigenvalues of a(n) are only  $\approx \mathbb{Z}(\lambda)$ .
- Therefore, the contribution of  $p \mid h$  should be trivial.

## Intuition II

$$a(n) = \prod_{p \mid \lambda} \frac{a(p^{\nu_p(n)})}{\chi(\overline{p})^{\nu_p(n)}} \cdot \chi_p\left(\frac{n}{p^{\nu_p(n)}}\right).$$

If  $\lambda$  is composite, we can separate one contribution:

$$a(n) \cdot \frac{\chi(\overline{q})^{\nu_q(n)}}{a(q^{\nu_q(n)})} \cdot \chi_q^{-1}\left(\frac{n}{q^{\nu_q(n)}}\right) = \prod_{\substack{\rho \mid \lambda \\ \rho \neq q}} \frac{a(p^{\nu_p(n)})}{\chi(\overline{\rho})^{\nu_p(n)}} \cdot \chi_p\left(\frac{n}{p^{\nu_p(n)}}\right).$$

- Continuous eigenvalues of the left-hand side:  $\approx \mathbb{Z}(\lambda)$ .
- Continuous eigenvalues of the right-hand side:  $\approx \mathbb{Z}(\lambda/q)$ .

$$a(n) = \frac{a(p^{\nu_p(n)})}{\chi(\overline{p})^{\nu_p(n)}} \cdot \chi_p\left(\frac{n}{p^{\nu_p(n)}}\right).$$

### Conclusion

- Capturing the independence of additive and multiplicative structures is hard.
- The intersection of automatic and multiplicative sequences is very special.
- Dynamics often gives you a good intuition.

## Thank you!
