Abstract. We study call-by-need from the point of view of the duality between call-by-name and call-by-value. We develop sequent-calculus style versions of call-by-need both in the minimal and classical case. As a result, we obtain a natural extension of call-by-need with control operators. This leads us to introduce a call-by-need λ\mu-calculus. Finally, by using the dualities principles of λ\mu-calculus, we show the existence of a new call-by-need calculus, which is distinct from call-by-name, call-by-value and usual call-by-need theories.

Keywords: call-by-need, lazy evaluation, duality of computation, sequent calculus, λ\mu-calculus, classical logic, control, subtraction connective

Introduction

The theory of call-by-name λ-calculus [9,8] is easy to define. Given the syntax of λ-calculus $M ::= x \mid \lambda x.M \mid MM$, the reduction semantics is entirely determined by the $\beta$-reduction rule $(\lambda x.M) N \rightarrow_\beta M[x \leftarrow N]$ in the sense that:

- for any closed term $M$, either $M$ is a value $\lambda x.N$ or $M$ is a $\beta$-redex and for all $M \rightarrow V$, there is standard path $M \rightarrow V'$ made only of $\beta$-redexes at the head, together with the property that $V' \rightarrow V$ using internal $\beta$-reductions;
- the observational closure of $\beta$ induces a unique rule $\eta$ that fully captures observational equality over finite normal terms (so-called Böhm’s theorem);
- the extension with control, typically done à la Parigot [29], is relatively easy to get by adding just two operational rules and an observational rule (though the raw version of Böhm’s theorem fails [15,34]).

The theory of call-by-value λ-calculus, as initiated by Plotkin [31], has a similar property with respect to the $\beta_c$ rule (the argument of $\beta$ being restricted to a variable or a $\lambda x.M$ only), but the observational closure is noticeably more

\* In order to keep a numbering a definitions and propositions consistent with the non-extended version, we adopt a specific numbering style for those definitions and propositions which were not present in the non-extended version, writing \texttt{LV.n} for the $n^{\text{th}}$ such statement.
complex: it at least includes the rules unveiled by Moggi [26] as was shown by Sabry and Felleisen [33]. Extensions of standardization and Böhm theorem for call-by-value are more delicate than in call-by-name [24,32].

Comparatively, call-by-need λ-calculus, though at the core of implementation languages such as Haskell [16], is in a rudimentary state of development as the first approach to it as a proper calculus goes back to the 90’s with the works of Ariola et al. [3] and Maraist et al. [25] for whom the concern was the characterization of standard weak-head reduction. Our paper is an attempt to raise the study of call-by-need to the same level of study as call-by-name, and in a slightly less extent call-by-value. In particular, we will address the question of adding control to call-by-need and the question of what is the dual of call-by-need along the lines of the duality between call-by-name and call-by-value [20,35,11]. Call-by-need is close to call-by-value in the sense that only values are substituted, but call-by-need is also close to call-by-name in the sense that only those terms that are bound to needed variables are evaluated. In particular, with respect to evaluation of pure closed terms, the call-by-name and call-by-need calculi are not distinguishable. In order to tackle the problem of developing a classical version of call-by-need, we first study how to formulate (minimal) call-by-need in the sequent calculus setting [22] (while current call-by-need calculi are based on natural deduction [31]). An advantage of a sequent calculus presentation of a calculus is that its extension to the classical case does not require the introduction of new rules but simply the extension of existing ones [7].

Curien and Herbelin [11] designed a calculus that provides an appealing computational interpretation of proofs in sequent calculus, while providing at the same time a syntactic duality between terms, i.e., producers, and evaluation contexts, i.e., consumers, and between the call-by-name and call-by-value reduction strategies. By giving priority to the producer one obtains call-by-value, whereas by giving priority to the consumer one obtains call-by-name. In this paper, we present how call-by-need fits in the duality of computation. Intuitively, call-by-need corresponds to focusing on the consumer to the point where the producer is needed. The focus goes then to the producer till a value is reached. At that point, the focus returns to the consumer. We call this calculus lazy call-by-value, it is developed in Section 2 and 3. In addition to the properties of confluence and standardization, we show its correctness with respect to the call-by-name sequent calculus [11]. In Section 4, we develop the natural deduction presentation of call-by-need. The reduction theory is contained in the one of Maraist et al. [25] and extends the one of Ariola et al. [3]. Interestingly, the sequent calculus has suggested an alternative standard reduction which consists of applying some axioms (i.e., lift and assoc) eagerly instead of lazily. In Section 5, we show that the natural deduction and sequent calculus call-by-need are in reduction correspondence. In Section 6, we extend the minimal sequent calculus call-by-need with control, in both sequent calculus and natural deduction form. The calculi still enjoy confluence and standardization. The sequent calculus presentation of call-by-need naturally leads to a dual call-by-need, which corresponds to focusing on the producer and going to the consumer on a need basis. We call
this calculus lazy call-by-name. In Section 7 we present abstract machine for our calculi. In Section 8 we show how the dual call-by-need is obtained by dualizing the lazy call-by-value extended with the subtraction connective. We conclude and discuss our future work in Section 9. We start next with an overview of the duality of computation.

1 The duality of computation

Curien and Herbelin [11] provided classical sequent calculus with a term assignment, which is called the $\lambda\mu_\tilde{\mu}$ calculus. In $\lambda\mu_\tilde{\mu}$ there are two dual syntactic categories: terms which produce values and contexts which consume values. The interaction between a producer $v$ and a consumer $e$ is rendered by a command written as $\langle v\|e \rangle$, which is the computational counterpart of a sequent calculus cut. Contexts can be seen as evaluation contexts, that is, commands with a hole, written as $\Box$, standing for the term whose computation is to be done next: $\langle \Box\|e \rangle$. Thus, a command $\langle v\|e \rangle$ can be seen as filling the hole of the evaluation context $e$ with $v$. Dually, terms can also be seen as commands with a context hole, standing for the context in which the term shall be computed. The duality of terms and contexts is also reflected at the variable level. One has two distinct sets of variables. The usual term variables ($x, y, \cdots$) and the context variables ($\alpha, \beta, \cdots$), which correspond to continuation variables. The set of terms, in addition to variables and lambda abstractions, contains a term of the form $\mu\alpha.c$, where $c$ is a command, after Parigot’s $\lambda\mu$-calculus [29]. The $\mu$ construct corresponds to Felleisen’s $C$ control operator [18,19,17]; one can read $\mu\alpha.c$ as $C(\lambda\alpha.c)$. Whereas the $\mu$ construct allows one to give a name to a context, so as to invoke it later, the dual construct, named $\tilde{\mu}$, allows one to name terms. One can read $\tilde{\mu}x.c$ as let $x = \Box$ in $c$. Given a context $e$, $v \cdot e$ is also a context, which corresponds to an applicative context of the form $e[\Box v]$. The grammar of $\lambda\mu\tilde{\mu}$ and its reduction theory are given below:

$$
\begin{align*}
c &::= (v\|e) & v &::= x \mid \lambda x.v \mid \mu\alpha.c \\
\langle \beta \rangle &\quad \langle \lambda x.v\|s \cdot e \rangle \rightarrow \langle s[\tilde{\mu}x.(v\|e)] \rangle \\
\langle \mu \rangle &\quad \langle \mu\alpha.c\|e \rangle \rightarrow c[\alpha \leftarrow e] \\
\langle \tilde{\mu} \rangle &\quad \langle v\|\tilde{\mu}x.c' \rangle \rightarrow c'[x \leftarrow v]
\end{align*}
$$

The reduction theory can be seen as consisting of structural reduction rules, $\mu$ and $\tilde{\mu}$, as well as logical reduction rules (here, only $\beta$, the rule corresponding to implication).

The calculus is not confluent due to a critical pair between $\mu$ and $\tilde{\mu}$:

$$
\langle z\|\beta \rangle \leftarrow \mu \langle \mu\alpha.(z\|\beta)\|\tilde{\mu}x.(y\|\beta) \rangle \rightarrow \tilde{\mu} \langle y\|\beta \rangle
$$

To regain confluence one can impose a strategy on how to resolve the critical pair $\mu/\tilde{\mu}$. By giving priority to the $\tilde{\mu}$ rule one captures call-by-name, whereas by giving priority to the $\mu$ rule one captures call-by-value. More generally, one can
describe various ways to specialize the pair $\mu/\tilde{\mu}$ as reduction rules parametrized by sets $E$ and $V$, which denote sets of contexts and terms, respectively:

\[
(\mu_E) \langle \alpha. c | e \rangle \rightarrow c[\alpha \leftarrow e] \quad \text{if } e \in E
\]

\[
(\tilde{\mu}_V) \langle v | \tilde{\mu}x.c' \rangle \rightarrow c'[x \leftarrow v] \quad \text{if } v \in V
\]

This presentation with parametric rules is inspired by the work of Ronchi and Paolini on parametric $\lambda$-calculus [32]. A strategy corresponds to specifying which contexts and terms can be duplicated or erased. For call-by-name, $E$ and $V$ are instantiated with the following sets $E_n$ and $V_n$:

\[
E_n ::= \alpha | v \cdot E_n \quad V_n ::= \lambda x.v | \mu\alpha.c
\]

resulting in reduction rules that we will denote as $\mu_n$ and $\tilde{\mu}_n$, respectively. For call-by-value, the instantiations are $E_v$ and $V_v$:

\[
E_v ::= \alpha | v \cdot E_v | \tilde{\mu}x.c \quad V_v ::= \lambda x.v
\]

resulting in reduction rules that we will denote as $\mu_v$ and $\tilde{\mu}_v$, respectively. In call-by-name (i.e., with $\mu_n/\tilde{\mu}_n$) every term is substitutable for a term variable, while only specific contexts can be substituted for a context variable. Dually, call-by-value (i.e., with $\mu_v/\tilde{\mu}_v$) restricts what is substituted for a term variable, but does not impose restrictions on substitution of contexts. Notice also that full non-deterministic $\lambda\tilde{\mu}\tilde{\nu}$ corresponds to choosing $\mu_v$ together with $\tilde{\mu}_n$. Call-by-need $\lambda\mu\tilde{\nu}$-calculus will be defined with respect to another choice of parameters.

Curien and Herbelin also developed a subcalculus of $\lambda\mu\tilde{\nu}$ called $\lambda\tilde{\mu}_T$ (after Danos et al’s LKT [12,13]), which restricts the syntax of legal contexts. This captures the intuition that according to the call-by-name continuation passing style, the continuation follows a specific pattern. The syntax of $\lambda\tilde{\mu}_T$ becomes:

\[
c ::= \langle v|e \rangle \quad v ::= V_n \quad e ::= \tilde{\mu}x.c | E_n
\]

Notice that whereas $v \cdot \tilde{\mu}x.c$ is a legal context in $\lambda\mu\tilde{\nu}$, it is not legal in $\lambda\tilde{\mu}_T$. The reduction theory of $\lambda\tilde{\mu}_T$ consists of $\beta$, $\mu_n$ and $\tilde{\mu}_n$.

In addition to the instantiations of the structural rules $\mu_E$ and $\tilde{\mu}_V$, the calculi developed in the rest of the paper will contain rules for evaluating connectives. We will only consider implication, except in Section 8 where subtraction will also be added. We will also consider the following extensionality rules:

\[
(\eta^\mu_V) \mu\alpha. \langle v | \alpha \rangle \rightarrow v \quad v \in V \text{ and } \alpha \text{ is not free in } v
\]

\[
(\eta^\mu_T) \tilde{\mu}x. \langle x | e \rangle \rightarrow e \quad e \in E \text{ and } x \text{ is not free in } e
\]

## 2 Call-by-need and duality

As we did for call-by-name and call-by-value, we have to specify the parametric sets used for call-by-need, that is, which terms and contexts can be substituted for term and context variables. Since call-by-need avoids duplication of work, it
is natural to restrict the set $\mathcal{V}$ to $V_n$, thus allowing substitution of variables and lambda abstractions only. One should allow the reduction of $\langle \mu \alpha.\langle I[I\cdot \alpha] \rangle \cdot v \cdot \alpha \rangle$ ($I$ stands for $\lambda x.x$) to $\langle I[I\cdot v \cdot \alpha] \rangle$ since the applicative redex is needed in order to continue the computation. This implies that $E_n$ should be part of $\mathcal{E}$. That however is not enough. One would also want to reduce $\langle \mu \alpha.\langle I[I\cdot \alpha] \rangle \cdot \tilde{\mu} x.\langle x|\alpha \rangle \rangle$ to $\langle I[I\cdot \tilde{\mu} x.\langle x|\alpha \rangle] \rangle$. This however does not imply that $\tilde{\mu} x.c$ should be part of $\mathcal{E}$ since that would unveil an unwanted redex, such as in $\langle \mu \alpha.\langle I[I\cdot \alpha] \rangle \cdot \tilde{\mu} x.\langle z|\alpha \rangle \rangle$.

The only time we want to allow a change of focus from the consumer to the producer is when the producer is needed, which means that the variable bound to the producer occurs in the hole of a context; $x$ is needed in $\langle x|E_n \rangle$ but it is not needed in $\langle x|\tilde{\mu} y.\langle z|\alpha \rangle \rangle$. This notion will still not capture a situation such as $\langle \mu \alpha.\langle I[I\cdot \alpha] \rangle \cdot \tilde{\mu} x.\langle v_1|\tilde{\mu} y.\langle x|E_n \rangle \rangle$, since the needed variable is buried under the binding for $y$. This motivates the introduction of the notion of a call-by-need meta-context, which is simply a hole surrounded by $\tilde{\mu}$-bindings:

$$C^\tilde{\mu}_I := \square \langle \mu \alpha.c \cdot \tilde{\mu} z.C^\tilde{\mu}_I \rangle$$

A variable $x$ is needed in a command $c$, if $c$ is of the form $C^\tilde{\mu}_I | \langle x|E_n \rangle$.

We have so far determined that $\mathcal{E}$ contains the call-by-name applicative contexts and contexts of the form $\tilde{\mu} x.C^\tilde{\mu}_I | \langle x|E_n \rangle$. This would allow the reduction of $\langle \mu \alpha.\langle I[I\cdot \alpha] \rangle \cdot \tilde{\mu} f.\langle f|\alpha \rangle \rangle$ to $\langle I[I\cdot \tilde{\mu} f.\langle f|\alpha \rangle] \rangle$. The problem is that the call-by-name applicative context considered so far does not contain a $\tilde{\mu}$. This is necessary to capture sharing. For example, in the above term $\langle I[I\cdot \tilde{\mu} f.\langle f|\alpha \rangle] \rangle$, the $\tilde{\mu} f$ captures the sharing of $f$. We need however to be careful about which $\tilde{\mu}$ we allow in the notion of applicative context. For example, we should disallow contexts such as $I \cdot \tilde{\mu} f.\langle z|f \cdot \alpha \rangle$ since they might cause unwanted computation. Indeed, in the following reduction the application of $I$ to $I$ is computed while it is not needed to derive the result:

$$\langle I[I\cdot \tilde{\mu} f.\langle z|f \cdot \alpha \rangle] \rangle \rightarrow \beta_\alpha \langle I[I\cdot \tilde{\mu} x.\langle x|\tilde{\mu} f.\langle z|f \cdot \alpha \rangle] \rangle \rightarrow \beta_\alpha \langle I[I\cdot \tilde{\mu} f.\langle z|f \cdot \alpha \rangle] \rangle \rightarrow \beta_\alpha \langle z|I\cdot \alpha \rangle.$$

This implies that a context $\tilde{\mu} x.c$ is allowed in an applicative context only if $c$ demands $x$.

We are ready to instantiate the structural and extensional rules; $\mathcal{V}$ and $\mathcal{E}$ are instantiated as follows, resulting in reduction rules denoted as $\mu_i$, $\tilde{\mu}_i$ and $\eta^\mu_i$:

$$V_{\alpha} := x \mid \lambda x.v \quad E_{\alpha} := F \mid \tilde{\mu} x.C^\tilde{\mu}_I | \langle x|F \rangle \rangle \quad \text{with} \quad F := \alpha \mid v \cdot E_{\alpha}$$

3 Minimal call-by-need in sequent form ($\lambda_{mbe}$)

A classical sequent calculus naturally provides a notion of control. However, one can restrict the calculus to be control-free by limiting the set of continuation variables to a single variable, conventionally written $\ast$, which is linearly used. This corresponds to the restriction to minimal logic $\mathbb{I}$. We introduce next the lazy call-by-value calculus, $\lambda_{mbe}$.
Definition 1. The syntax of $\lambda_{mlv}$ is defined as follows:

- **command**: $c ::= \langle v \| e \rangle$
- **meta-context**: $C ::= \emptyset \mid (\mu^* \cdot c) \mu z . C$
- **term**: $v ::= x \mid \lambda x . v \mid \mu^* c$
- **applicative context**: $F ::= * \mid v \cdot E$
- **linear context**: $E ::= F \mid \mu x . C[\langle x \| F \rangle]$
- **context**: $e ::= E \mid \mu x . c$

The reduction of $\lambda_{mlv}$, written as $\rightarrow_{mlv}$, denotes the compatible closure of $\beta$, $\mu_1$, $\mu_v$ and $\eta^*_{\mu}$, the relation $\rightarrow_{mlv}$ denotes the reflexive and transitive closure of $\rightarrow_{mlv}$. The notion of weak head standard reduction is defined as:

$\frac{c \rightarrow_{\beta} c'}{C[\| c \|] \rightarrow_{mlv} C[\| c' \|]} \quad \frac{c \rightarrow_{\mu} c'}{C[\| c \|] \rightarrow_{mlv} C[\| c' \|]} \quad \frac{c \rightarrow_{\mu_v} c'}{C[\| c \|] \rightarrow_{mlv} C[\| c' \|]}$

The notation $\rightarrow_{mlv}$ stands for the reflexive and transitive closure of $\rightarrow_{mlv}$.

A weak head normal form (whnf) is a command $c$ such that for no $c'$, $c \rightarrow_{mlv} c'$.

Notice how in the lazy call-by-value calculus, the standard redex does not necessarily occur at the top level, in $\langle \nu_1 \mu x_1 . \langle \nu_2 \mu x_2 . (\lambda x . v) \cdot * \rangle \rangle$, the standard redex is buried under the bindings for $x_1$ and $x_2$, which is why the standard reduction refers to the meta-context. This however can be solved simply by going to a calculus with explicit substitutions, which would correspond to the abstract machine given in section 7. Note that in a term of the form $\langle \lambda z . v \mu x . \langle x \mu y . \langle y \| * \rangle \rangle \rangle$, the substitution for $y$ is not the standard redex, and in

$$\langle \mu^* , (I \| * \rangle) \mu x . \langle x \| \mu y . \langle y \| * \rangle \rangle \rangle \quad \langle \mu^* , (V \| * \rangle) \mu x . \langle x \| * \rangle \rangle$$

the standard redex is the underlined one. The $\eta^*_{\mu}$ rule is not needed for standard reduction. The $\eta^*_{\mu}$ rule turns a computation into a value, allowing for example $\langle \mu^* , (V \| * \rangle) \mu x . \langle y \| * \rangle \rangle \rightarrow \langle V \| \mu x . \langle y \| * \rangle \rangle \rightarrow \langle y \| V \| * \rangle$, which is not a standard reduction; in fact, the starting term is already in whnf.

Proposition 1. $\rightarrow_{mlv}$ is confluent.

Proof. The only critical pair in $\lambda_{mlv}$ is between $\eta^*_{\mu}$ and $\mu_1$ and it trivially converges since both rules produce the same resulting command. \qed

Remark 1. In $\lambda_{mlv}$ the duplicated redexes are all disjoint. This was not the situation in $\lambda_{need}$ [25], where the assoc rule could have duplicated a lift redex. This does not happen in $\lambda_{mlv}$ because the contexts are moved all at once, as described in the example below, which mimics the situation in $\lambda_{need}$.

$$\langle \mu^* , \langle z \| \mu y . \langle y \| * \rangle \rangle \rangle \mu x . \langle x \| * \rangle \rangle \rangle \rightarrow_{\mu_\alpha} \langle \mu^* , \langle z \| \mu y . \langle y \| \mu x . \langle x \| * \rangle \rangle \rangle \rangle \mu x . \langle x \| * \rangle \rangle \rangle \rightarrow_{\mu_\alpha} \langle z \| \mu y . \langle y \| * \rangle \rangle \rangle \mu x . \langle x \| * \rangle \rangle \rangle$$
The needed constraint breaks the property that commands in weak head normal form are of the form $\langle x \mid E \rangle$ or $\langle \lambda x. v \mid \star \rangle$ (a property that holds for $\lambda \mu \tilde{\mu}$ in call-by-name or call-by-value).

**Definition 2.** Let $x$ be a sequence of variables. $c_x$ is defined by the grammar:

$$c_x ::= \langle \mu \ast. c \tilde{\mu} y. c_{y[x]} \rangle \mid \langle \lambda x. v \mid \star \rangle \mid \langle \mu \ast. \langle z \mid F \rangle \rangle.$$  

$z \notin x$.

**Proposition 2.** A command $c$ is in weak head normal form if it is in $c_\epsilon$, where $\epsilon$ denotes the empty sequence of variables.

**Proof.** Any command in $c_\epsilon$ is indeed in whnf. Conversely, if $c$ is in whnf, there is no $c'$ such that $c \rightarrow_{mlv} c'$ by definition, which means that $c$ must be either of the form $C[\langle \lambda x. v \mid \star \rangle]$ or $C[\langle z \mid F \rangle]$ with $z$ not bound by a $\tilde{\mu}$, otherwise said it must be in $c_\epsilon$.

Note that in $c_x$, $x$ records the variables which are $\tilde{\mu}$-bound to a computation on the path from the top of the term to the current position. $\langle x \mid \star \rangle$ is in whnf, however it is not of the form $c_x$ since it demands variable $x$. Neither $\langle y \tilde{\mu} x. c \rangle$ nor $\langle \mu \ast. c \tilde{\mu} x \rangle$ are in whnf. A whnf is either of the form $C[\langle x \mid F \rangle]$ or $C[\langle \lambda x. v \mid \star \rangle]$.

**Proposition 3 (Unique Decomposition).** A command $c$ is either a whnf or there exists a unique meta-context $C$ and redex $c'$ such that $c$ is of the form $C[c']$.

**Proof.** (sketch). It is easy to see that standard redexes are mutually exclusive. For instance, a command $c$ which had a standard $\beta$ redex cannot have a $\mu_l$ or $\tilde{\mu}_v$ redex.

**Proposition 4 (Standardization).** Given a command $c$ and a whnf $c'$, if $c \rightarrow_{mlv} c'$ then there exists a whnf $c''$ such that $c \rightarrow_{mlv} c''$ and $c'' \rightarrow_{mlv} c'$.

### 3.1 Soundness and Completeness of $\lambda_{mlv}$

The $\lambda_{mlv}$ calculus is sound and complete with respect to the minimal restriction of the call-by-name sequent calculus, $\lambda \mu \tilde{\mu} T$. We first need to translate $\lambda_{mlv}$ terms to $\lambda \mu \tilde{\mu} T$ terms by giving a name to the $\tilde{\mu}$-term contained in a linear context. The translation, written as $(\cdot)^\circ$, is defined as follows (the only interesting cases of the translation are the last two cases), with $n \geq 0$:

$$x^\circ = x$$
$$\lambda x. v^\circ = \lambda x. v^\circ$$
$$\mu \star. c^\circ = \mu \star. c$$
$$\langle v \mid w_1 \ldots w_n \cdot \ast \rangle^\circ = \langle v^\circ \mid w_1^\circ \ldots w_n^\circ \cdot \ast \rangle$$
$$\langle v \tilde{\mu} x. c \rangle^\circ = \langle v^\circ \tilde{\mu} x. c^\circ \rangle$$
$$\langle v \tilde{\mu} x. c \rangle^\circ = \langle v^\circ \tilde{\mu} x. c^\circ \rangle$$

we then have the following properties:
Lemma LV.1. If c is a command in $\lambda_{mlv}$, then $c^\circ$ is a command in $\lambda_{\tilde{\mu}T}$.

Proof. The syntactical constraint on $\lambda_{\tilde{\mu}T}$ commands is that a context is either of the form $\tilde{\mu}x.c$ or it is a stack a terms pushed on top of $\ast$. The translation precisely achieves this goal. \qed

Proposition 5. (i) Given a $\lambda_{mlv}$ term v, $v =_{mlv} v^\circ$.
(ii) Given $\lambda_{\tilde{\mu}T}$ terms v and w:
(a) $v =_{mlv} w$ then $v =_{\tilde{\mu}T} w$;
(b) $v =_{\tilde{\mu}T} (\lambda x.w\|\ast)$ then $v =_{mlv} C[(\lambda x.w'|\ast)]$ for some C and w'.

Indeed, $\lambda_{mlv}$ theory restricted to the call-by-name syntax of $\lambda_{\tilde{\mu}T}$ is included in $\lambda_{\tilde{\mu}T}$ theory.

Intermezzo 2 Soundness can also be shown with respect to the $\lambda_{\tilde{\mu}}$ calculus without the need of doing a translation, since the $\lambda_{\tilde{\mu}}$ calculus does not impose any restrictions on the context. This however requires extending the $\tilde{\mu}$ rule to \langle v|v_1\cdots v_n,\tilde{\mu}x.c \rangle$ \rightarrow c|x = \mu\ast,\langle v|v_1\cdots v_n,\ast \rangle$. The rule is sound for call-by-name extended with the eta rule, called $\eta^{\circ}$ in [23], given as $y = \lambda x.\alpha.(y|\mu x.\alpha)$.

4 Minimal call-by-need in Natural Deduction ($\lambda_{need}$)

We now present the call-by-need calculus inspired by the sequent calculus.

Definition 3. The syntax of $\lambda_{need}$ is defined as follows:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Term</th>
</tr>
</thead>
<tbody>
<tr>
<td>term</td>
<td>$M ::= V</td>
</tr>
<tr>
<td>term value</td>
<td>$V ::= x</td>
</tr>
<tr>
<td>computation</td>
<td>$M_{nv} ::= MM \mid \text{let } x = M \text{ in } N$</td>
</tr>
<tr>
<td>applicative context</td>
<td>$C_{ap} ::= \Box \mid C_{ap}M$</td>
</tr>
<tr>
<td>needed context</td>
<td>$C ::= C_{ap} \mid \text{let } x = M_{nv} \text{ in } C \mid \text{let } x = C_{ap}M \text{ in } C[x]$</td>
</tr>
</tbody>
</table>

Reduction in $\lambda_{need}$, written as $\rightarrow_{need}$, is the compatible closure of the following rules:

- (\beta) $(\lambda x.N)M \rightarrow_{\text{\beta, lift}} \text{let } x = M \text{ in } N$
- (lift) $(\text{let } x = M \text{ in } P)N \rightarrow_{\text{\beta, lift}} \text{let } x = M \text{ in } PN$
- (deref_v) $\text{let } z = V \text{ in } M \rightarrow_{\text{deref_v}} M[x ← V]$
- (assoc) $\text{let } z = (\text{let } x = M \text{ in } N) \text{ in } C[z] \rightarrow_{\text{assoc}} \text{let } x = M \text{ in } \text{let } z = N \text{ in } C[z]$

The relation $\rightarrow_{\text{need}}$ denotes the reflexive and transitive closure of $\rightarrow_{\text{need}}$.

The notion of weak head standard reduction is defined as:

$$M \rightarrow_{\beta, lift} N \quad \frac{C_{\beta l}[M] \rightarrow_{\text{need}} C_{\beta l}[N]}{C_{\beta l}[M] \rightarrow_{\text{need}} C_{\beta l}[N]} \quad \frac{M \rightarrow_{\text{deref_v, assoc}} N}{C_{da}[M] \rightarrow_{\text{need}} C_{da}[N]}$$

where

- $C_{\beta l} ::= C_{ap} \mid \text{let } x = M_{nv} \text{ in } C_{\beta l} \mid \text{let } x = C_{ap} \text{ in } C[x]$
- $C_{da} ::= \Box \mid \text{let } x = M_{nv} \text{ in } C_{da}$
The notation $\rightarrow_{\text{need}}$ stands for the reflexive and transitive closure of $\rightarrow_{\text{need}}$. A weak head normal form (w hf ) is a term $M$ such that for no $N$, $M \rightarrow_{\text{need}} N$.

Unlike the calculi defined by Maraist et al. [25] and Ariola et al. [3], the \textit{deref}_v rule follows the call-by-value discipline since it substitutes a value for each occurrence of the bound variable, even if the variable is not needed. The rule is derivable in the calculus of Maraist et al. using garbage collection. The \textit{assoc} rule is more constrained than in the calculus of Maraist et al. since it performs the flattening of the bindings on a demand basis. The \textit{assoc} requires the variable to appear in the hole of a context $C$, whose definition does not allow a hole to be bound to a let variable. For example, let $x = \square$ in $x$ and let $x = \square$ in $y = x$ in $y$ are not $C$ contexts. This restriction is necessary to make sure that in a term of the form

$$\text{let } x = (\text{let } z = N \text{ in } P) \text{ in } y$$

the standard redex is the substitution for $y$ and not the \textit{assoc} redex. The \textit{assoc} rule is more general than in [3], since it does not require the binding for $z$ to be an answer (i.e., an abstraction surrounded by bindings). The lift rule is the same as in [25], it is more general than the corresponding rule in [3] since the left-hand side of the application is not restricted to be an answer. The calculi in [25] and [3] share the same standard reduction. For example, in the terms:

$$(\lambda x.x) y$$

$$(\lambda x. x) y$$

is the standard redex. Our standard reduction differs. The above terms correspond to a lift and assoc redex, respectively. Moreover, our standard reduction is also defined for open terms. Thus, the following terms:

$$\text{let } y = x z \text{ in } y P$$

$$\text{let } y = (\text{let } z = N \text{ in } P) \text{ in } y$$

instead of being of the form $C[x]$, reduce further. The standard reduction requires different closure operations to avoid the interference between reductions. In

$$\text{let } z = (\text{let } x = V \text{ in } N) \text{ in } z \text{ and } \text{let } y = (\text{let } z = (\text{let } x = M \text{ in } N) \text{ in } P) \text{ in } y$$

the standard redex is the (outermost) assoc, and in let $x = \Pi$ in $y = x$ in $y$, the \textit{deref}_v is the standard redex.

**Proposition 6.** $\rightarrow_{\text{need}}$ is confluent.

**Proof. (sketch)** We simply show how the critical pairs converge:

- \textit{lift/assoc}:

  $$Q_0 \leftarrow_{\text{lift}} (\text{let } z = (\text{let } x = M \text{ in } N) \text{ in } C[z])P \rightarrow_{\text{assoc}} Q_1$$

  with $Q_0 \triangleq (\text{let } z = (\text{let } x = M \text{ in } N) \text{ in } C[z])P$ and $Q_1 \triangleq (\text{let } x = M \text{ in } N \text{ in } C[z])P$. It is clear that $C[z]P$ reduces to a $C'[z]$ after a certain number of applications of the lift rule (possibly 0) and thus that

  $$Q_1 \rightarrow_{\text{lift}} \text{let } x = M \text{ in } (\text{let } z = N \text{ in } C[z])P$$

  $$\rightarrow_{\text{lift}} \text{let } x = M \text{ in } \text{let } z = N \text{ in } C[z]P$$

  $$\rightarrow_{\text{lift}} \text{let } x = M \text{ in } \text{let } z = N \text{ in } C'[z] \leftarrow_{\text{assoc}} \leftarrow_{\text{lift}} Q_0$$
- **lift/deref<sub>v</sub>:**
  \[ Q_0 \leftarrow \text{lift} \ (\text{let } x = V \text{ in } C[x])P \rightarrow_{\text{deref}<sub>v</sub>} Q_1 \]
  with \( Q_0 \triangleq \text{let } x = V \text{ in } C[z]P \) and \( Q_1 \triangleq C[x][x \leftarrow V]P \leftarrow_{\text{deref}<sub>v</sub>} Q_0 \).

- **assoc/deref<sub>v</sub>:**
  \[ Q_0 \leftarrow_{\text{deref}<sub>v</sub>} \text{let } x = (\text{let } y = V \text{ in } M) \text{ in } C[x] \rightarrow_{\text{assoc}} Q_1 \]
  with \( Q_0 \triangleq \text{let } x = M[y \leftarrow V] \text{ in } C[x] \) and \( Q_1 \triangleq \text{let } y = V \text{ in } \text{let } x = M \text{ in } C[x] \rightarrow_{\text{assoc}} (\text{let } x = M \text{ in } C[x])[y \leftarrow V] = Q_0 \).

- **assoc/assoc:**
  \[ Q_0 \leftarrow_{\text{assoc}} \text{let } x = (\text{let } y = (\text{let } z = M \text{ in } N) \text{ in } C[y]) \text{ in } C'[x] \rightarrow_{\text{assoc}} Q_1 \]
  with \( Q_0 \triangleq \text{let } y = (\text{let } z = M \text{ in } N) \text{ in } \text{let } x = C[y] \text{ in } C'[x] \) and \( Q_1 \triangleq \text{let } x = (\text{let } z = M \text{ in } \text{let } y = N \text{ in } C[y]) \text{ in } C'[x] \).
  
  If \( C[y] = y \) then (writing \( C''[y] \) for \( C'[x][x \leftarrow y] \)):

  \[
  \begin{align*}
  Q_0 & \rightarrow_{\text{deref}<sub>v</sub>} \text{let } y = (\text{let } z = M \text{ in } N) \text{ in } C''[y] \\
  & \rightarrow_{\text{assoc}} \text{let } z = M \text{ in } \text{let } y = N \text{ in } C''[y] \\
  Q_1 & \rightarrow_{\text{assoc}} \text{let } z = M \text{ in } \text{let } y = N \text{ in } C''[y] \\
  & \rightarrow_{\text{assoc}} \text{let } z = M \text{ in } \text{let } y = N \text{ in } C''[y] \\
  & \rightarrow_{\text{deref}<sub>v</sub>} \text{let } z = M \text{ in } \text{let } y = N \text{ in } C''[y]
  \end{align*}
  \]

  Otherwise, \( C[y] = M_{>v} \) and

  \[
  \begin{align*}
  Q_0 & \rightarrow_{\text{assoc}} \text{let } z = M \text{ in } \text{let } y = N \text{ in } \text{let } x = C[y] \text{ in } C'[x] \\
  Q_1 & \rightarrow_{\text{assoc}} \text{let } z = M \text{ in } \text{let } y = N \text{ in } \text{let } x = C[y] \text{ in } C'[x] \\
  & \rightarrow_{\text{assoc}} \text{let } z = M \text{ in } \text{let } y = N \text{ in } \text{let } x = C[y] \text{ in } C'[x]
  \end{align*}
  \]

\[ \square \]

**Proposition 7 (Unique Decomposition).** *A term \( M \) is either a whnf or there exists a unique \( C_{\beta} \) such that \( M \) is of the form \( C_{\beta}[P] \), where \( P \) is a \( \beta \) or lift redex, or there exists a unique \( C_{da} \) such that \( M \) is of the form \( C_{da}[P] \), where \( P \) is a deref<sub>v</sub> or assoc redex.*

The following lemma, which is immediate, is useful in order to obtain the previous propositions

**Lemma LV.2.**

- \( C[x] \) is a whnf and
- \( C_{da} \subset C \subset C_{\beta} \).

**Proof.** (sketch for proposition 7) The unique decomposition proposition is proved by a simple check that cases for weak head redexes are mutually exclusive. \( \square \)
Proposition 8 (Standardization). Given a term \( M \) and \( \text{whnf} \) \( N \), if \( M \rightarrow \text{need} \ N \) then there exists a \( \text{whnf} \) \( N' \) such that \( M \rightarrow \text{need} \ N' \) and \( N' \rightarrow \text{need} \ N \).

Definition 4. Let \( x \) be a sequence of variables. \( M_x \) is defined as:
\[
M_x := \lambda x.N \mid \text{let } y = N_{nv} \text{ in } M_{y x} \mid z N_1 \cdots N_n \mid \text{let } y = z N_1 \cdots N_n \text{ in } C[y] \mid z \not\in x
\]

Proposition 9. A term \( M \) is in \( \text{whnf} \) if and only if it is in \( M_c \) (with \( c \) the empty sequence).

4.1 Soundness and completeness of \( \lambda_{\text{need}} \)

Our calculus is sound and complete for evaluation to an answer (i.e., an abstraction or a let expression whose body is an answer) with respect to the standard reduction of the call-by-need calculi defined in [25] and [3], denoted by \( \rightarrow_{\text{af}} \).

Proposition 10. Let \( M \) be a term and \( A \) be an answer.
- If \( M \rightarrow \text{need} \ A \) then there exists an answer \( A' \) such that \( M \rightarrow_{\text{af}} A' \);
- If \( M \rightarrow_{\text{af}} A \) then there exists an answer \( A' \) such that \( M \rightarrow \text{need} \ A' \).

Proof. Discussion at the beginning of the section evidences that \( \rightarrow_{\text{need}} \) is contained in \( \rightarrow_{\text{mow}} \) and contains \( \rightarrow_{\text{af}} \). The result follows from the fact that standard reductions of \( \rightarrow_{\text{mow}} \) and \( \rightarrow_{\text{af}} \) coincide. \( \square \)

5 Correspondence between \( \lambda_{\text{mlv}} \) and \( \lambda_{\text{need}} \)

The calculi \( \lambda_{\text{mlv}} \) and \( \lambda_{\text{need}} \) are in reduction correspondence for the following translations from \( \lambda_{\text{need}} \) to \( \lambda_{\text{mlv}} \) and vice-versa:

Definition 5. Given a term \( M \) in \( \lambda_{\text{need}} \), a term \( v \), a context \( c \) and a command \( c^a \) in \( \lambda_{\text{mlv}} \), translations \( M^\circ \), \( M^\circ_e \), \( v^c \), \( \star^a \) and \( \star^a \) are defined as follows:
\[
\begin{align*}
\lambda x.M^\circ &= \lambda x.M^\circ \quad V^c_e = (V^c | e) \\
(MN)^\circ &= \mu^* \cdot (MN)^\circ \quad (\text{let } x = M \text{ in } N)^\circ = \mu^* \cdot (\text{let } x = M \text{ in } N)^\circ \\
(MN)^c_e &= M^c_{N^c-e} \\
(\text{let } x = M \text{ in } N)^c_e &= \begin{cases} 
M^c_{N^c} & N \in C[x] \\
(M^c | \mu^* x. N^c) & \text{otherwise}
\end{cases}
\end{align*}
\]
\[
\begin{align*}
(x^c)^c &= x \quad \mu^* \cdot \mu^* = \square \\
(\lambda x.v)^c &= \lambda x.v^c \quad (v \cdot E)^c = E^c[\square v^c] \\
(\mu^* x. c)^c &= c^c \quad (\mu x. c)^c = \text{let } x = \square \text{ in } c^c
\end{align*}
\]

We first illustrate the correspondence on an example.

Example 3 Consider the following \( \lambda_{\text{need}} \) reduction, where \( I \) stands for \( \lambda y.y \) and \( M \) for \( (\lambda f.fI(fI))((\lambda z.zw.zw)(II)) \):
\[
M \rightarrow_{\beta} \text{let } f = (\lambda z.zw.zw)(II) \rightarrow_{\beta} \text{let } z = II \rightarrow_{\text{assoc}} \text{let } f = \lambda w.zw \text{ in } fI(fI)
\]

11
We have $M^\circ = \langle \lambda f.\mu^\star.\langle f \cdot (fI)^\circ \cdot \star \rangle \rangle \mu^\star.\langle \lambda z.\lambda w.\langle zw \rangle^\circ \rangle \langle (II)^\circ \cdot \star \rangle \cdot \star \rangle$. The first $\beta$ step is simulated by the following $\lambda_{mlv}$ reduction, where we underline the redex to be contracted unless it occurs at the top:

\[
\langle \lambda f.\mu^\star.\langle f \cdot (fI)^\circ \cdot \star \rangle \rangle \mu^\star.\langle \lambda z.\lambda w.\langle zw \rangle^\circ \rangle \langle (II)^\circ \cdot \star \rangle \cdot \star \rangle \rightarrow_\beta \\
\langle \mu^\star.\langle \lambda z.\lambda w.\langle zw \rangle^\circ \rangle \langle (II)^\circ \cdot \star \rangle \rangle \rightarrow_\mu \\
\langle \mu^\star.\langle \lambda z.\lambda w.\langle zw \rangle^\circ \rangle \langle (II)^\circ \cdot \star \rangle \rangle \rightarrow_\mu \\
\langle \lambda z.\lambda w.\langle zw \rangle^\circ \rangle \langle (II)^\circ \cdot \star \rangle \rangle \\
\langle (II)^\circ \cdot \mu f.\langle f \cdot (fI)^\circ \cdot \star \rangle \rangle
\]

The second $\mu$ step corresponds to moving the redex in the context let $f = \Box$ in $C[f]$ at the top. The simulation of the second $\beta$ step leads to:

\[
\langle (II)^\circ \cdot \mu z.\langle \lambda w.\langle zw \rangle^\circ \rangle \mu f.\langle f \cdot (fI)^\circ \cdot \star \rangle \rangle
\]

The $assoc$ corresponds to an identity in $\lambda_{mlv}$.

Notice that the restriction on the $assoc$ rule is embedded in the sequent calculus. The simulation of a non restricted $assoc$ would require a generalization of the $\mu$ rule. For example, the simulation of the reduction:

\[
\text{let } x = (\text{let } y = II \text{ in } y) \text{ in } 0 \rightarrow \text{let } y = II \text{ in let } x = y \text{ in } 0
\]

would require equating the following terms:

\[
\langle \mu^\star.\langle I \cdot \tilde{\mu} y.\langle y \cdot \star \rangle \rangle \rangle \mu x.\langle 0 \cdot \star \rangle \rangle = \langle \mu^\star.\langle I \cdot \star \rangle \rangle \mu y.\langle y \cdot \tilde{\mu} x.\langle 0 \cdot \star \rangle \rangle
\]

However, those should not be equated to $\langle I \cdot \mu y.\langle y \cdot \tilde{\mu} x.\langle 0 \cdot \star \rangle \rangle \cdot \star \rangle$. That would correspond to relaxing the restriction of $E_1$ in the $\mu$ rule, and has the problem of bringing the redex $II$ to the top and thus becoming the standard redex.

**Proposition 11.** Call-by-need reduction in natural deduction and sequent form are in reduction correspondence:

(i) $M \rightarrow_{\text{need}} M^{\circ}$

(ii) $c \rightarrow_{\text{mlv}} c^{\circ}$

(iii) If $M \rightarrow_{\text{need}} N$ then $M^{\circ} \rightarrow_{\text{mlv}} N^{\circ}$

(iv) If $c \rightarrow_{\text{mlv}} c^{\circ}$ then $c^{\circ} \rightarrow_{\text{need}} c^{\circ}$

The previous proposition can be seen as an instance of proposition 14 studied in the next section.

**Remark 4** Note that the translation $(\_)_c$ of a let expression depends on the bound variable being needed or not. The choice of this optimized translation was required to preserve reduction. Indeed, otherwise, to simulate the $assoc$ reduction one would need an expansion in addition to a reduction.

6 Classical call-by-need in sequent ($\lambda_{cbn}$) and natural deduction form ($\lambda_{\text{need}}$)

Defining sequent classical call-by-need, called $\lambda_{cbn}$, requires extending the applicative context and the $\mu$ construct to include a generic continuation variable $\Box$. The

\[\text{To reduce closed commands one can introduce a constant named } \text{tp as in } [5], \text{ or one can encode the top-level using subtraction (see Section 8).}\]
syntax of $\lambda_{tv}$ becomes:

$$
c ::= \langle v | e \rangle \\
C ::= \Box \mid \langle \mu \alpha . c \| \mu z . C \rangle \\
v ::= x \mid \lambda x . v \mid \mu \alpha . c \\
e ::= E \mid \mu x . c
$$

Reduction, weak head standard reduction (written as $\to_{tv}$ and $\to_{tv}$, respectively) and weak head normal form (whnf) are defined as in the minimal case by replacing $\ast$ with any context variable $\alpha$. For example, a term of the form $\langle \mu \alpha . \langle x | \beta \rangle \| \mu x . \langle y | y \cdot \delta \rangle \rangle$ is in weak head normal form.

Unique decomposition, confluence and standardization extend to the classical case. Once control is added to the calculus, call-by-need and call-by-name are observationally distinguishable, as witnessed by the example given in the next section. It is important to notice that the bindings are not part of the captured context. For example, in the following command, the redex $\mu \alpha . \langle \lambda x . x \rangle (\langle \lambda x . x \rangle \cdot \alpha)$ will be executed only once. Whereas, if the bindings were part of the captured context then that computation would occur twice.

$$\langle II | \mu z . \langle \mu \alpha . \langle \lambda x . \mu \beta . \langle z | (\mu \delta . \langle \lambda x . x | \alpha \rangle ) \cdot \beta \rangle | \alpha \rangle | \mu f . \langle f | f \cdot z | \gamma \rangle \rangle \rangle$$

Unlike the sequent calculus setting, to extend minimal natural deduction to the classical case, we need to introduce two new constructs: the capture of a continuation and the invocation of it, written as $\mu \alpha . J$ and $[\alpha]M$, where $J$ stands for a jump (i.e., an invocation of a continuation). The reduction semantics makes use of the notion of structural substitution, which was first introduced in [29] and is written as $J[\alpha \leftarrow [\alpha]F]$ indicating that each occurrence of $[\alpha]M$ in $J$ is replaced by $[\alpha]F[M]$, where $F$ is the context captured by a continuation which is either $\Box M$ or let $x = \Box$ in $C[x]$. The benefits of structural substitution are discussed in [4]. In addition to lift, assoc, deref, and $\beta$, the reduction theory includes the following reduction rules:

$$(\mu_{ap}) \quad (\mu \alpha . J) M \quad \quad \rightarrow \quad \mu \alpha . J[\alpha \leftarrow [\alpha] (\Box M)]$$

$$(\mu_{let}) \quad \text{let } x = \mu \alpha . J \text{ in } C[x] \quad \quad \rightarrow \quad \mu \alpha . J[\alpha \leftarrow [\alpha] \text{ (let } x = \Box \text{ in } C[x])]$$

$$(\mu_{lift}) \quad \text{let } x = M_{\mu v} \text{ in } \mu \alpha . [\beta] N \quad \rightarrow \quad \mu \alpha . [\beta] \text{ (let } x = M_{\mu v} \text{ in } N)$$

$$(\mu_{base}) \quad [\beta] \mu \alpha . J \quad \rightarrow \quad J[\alpha \leftarrow \beta]$$

The relation $\rightarrow_{\mu_{tv}}$ denotes the compatible closure of $\rightarrow$, and $\rightarrow_{\mu_{tv}}$ denotes the reflexive and transitive closure of $\rightarrow_{\mu_{tv}}$. The weak head standard reduction is defined as follows:

$$M \rightarrow_{\beta, \mu_{tv}, \mu_{ap}} N \quad M \rightarrow_{\beta, \mu_{tv}, \mu_{let}, \mu_{lift}} N \quad M \rightarrow_{\beta, \mu_{tv}, \mu_{deref}, \mu_{let}, \mu_{assoc}, \mu_{lift}, \mu_{base}} N \quad J \rightarrow_{\mu_{tv}} J'$$

The notation $\rightarrow_{\mu_{tv}}$ stands for the reflexive and transitive closure of $\rightarrow_{\mu_{tv}}$.

Note that we only reduce jumps. A weak head normal form (whnf) is a term $M$ such that for no $N, M \rightarrow_{\mu_{tv}} N$. For example, let $x = \mu \alpha . [\beta] P$ in $yx$ is in whnf.

**Proposition 12.** $\rightarrow_{\mu_{tv}}$ is confluent.
Proposition 13. Given a term $M$ and $\text{whnf} N$, if $M \rightarrow_{\text{mu}} N$ then there exists a $\text{whnf} N'$ such that $M \rightarrow_{\text{mu}} N'$ and $N' \rightarrow_{\text{mu}} N$.

The translation between classical call-by-need in natural and sequent form is modified in the following way to cover the classical constructs:

$$\begin{align*}
(\mu \alpha . J)^{\circ} & = \mu \alpha . J^{\circ} \\
\alpha^{\circ} & = \alpha \\
\alpha_v.E & = \alpha E \\
\alpha_{\beta x}.(v|\beta) & = \alpha_v.\beta x \\
\mu \alpha.c^{\circ} & = \mu \alpha.c^{\circ}
\end{align*}$$

Proposition 14. Classical call-by-need in natural deduction and sequent form are in equational correspondence:

(i) $M =_{\text{mu}} M^{\circ}$

(ii) $c =_{\text{lv}} c^{\circ}$

(iii) If $M =_{\text{mu}} N$ then $M^{\circ} =_{\text{lv}} N^{\circ}$

(iv) If $c =_{\text{lv}} c'$ then $c^{\circ} =_{\text{mu}} c^{\circ}$

Notice that the main reason for having only equational correspondence instead of a more precise reduction correspondence is the fact that, in $\lambda_{\mu}\text{need} \cdot \mu_{ap}$ can be applied atomically $(\mu \alpha . J).N_1 \ldots N_n \rightarrow_{\mu_{ap}} (\mu \alpha . J[\alpha \leftarrow [\alpha][\Box N_1]] N_2 \ldots N_n$ while in $\lambda_{\text{lv}}$ the whole applicative context $\Box N_1 \ldots N_n$ is moved at once. In particular the following reduction still holds $c \rightarrow_{\text{lv}} c'$ then $c^{\circ} \rightarrow_{\text{mu}} c^{\circ}$.

7 Abstract Machines for Call-by-need

An abstract machine realizes the standard reduction in a tail recursive manner. To that end, a command is paired with an ordered list of declarations for regular and continuation variables. We directly present the abstract machine for the classical case, and then discuss how to restrict it to the minimal case. We assume that $\tau_0$ does not contain a binding for either $x$ or $\alpha$.

\[
\begin{array}{|c|}
\hline
\text{State} & \text{sl} ::= c\tau \\
\text{Binding} & \tau ::= [x=t] | [\alpha=F] | [\alpha = \mu x.(x|F)\tau] \\
\text{Binding vector} & \tau ::= \epsilon | \tau\tau \\
\hline
\end{array}
\]

\[
\begin{array}{|c|}
\hline
\langle t|\mu x.c \rangle \tau & \sim_{\text{lv}} c[x=t]\tau \\
\langle \mu x.c | F \rangle \tau & \sim_{\text{lv}} c|\alpha=F|\tau \\
\langle x | t \cdot E \rangle \tau & \sim_{\text{lv}} \langle V | t \cdot E \rangle \tau \quad \text{if} \quad \tau = \tau_0[x=V]\tau_1 \\
& \left\{ \begin{array}{l}
\langle c|\alpha = \mu x.(x|t \cdot E)\tau_0 |\tau_1 \\
\langle (V|\alpha) | \tau \\
\end{array} \quad \text{if} \quad \tau = \tau_0[x=V]\tau_1 \\
\langle x | F \rangle \tau \quad \text{if} \quad \tau = \tau_0[\alpha = \mu y.(y|F)\tau]\tau_1 \land [x=V] \notin \tau \\
\langle c|\beta = \mu x.(x|\beta)\tau_0 |\tau_1 \\
\langle \lambda x.t | s \cdot E \rangle \tau & \sim_{\text{lv}} \langle s|\mu x.(t|E)\rangle \tau \\
\langle \lambda x.t | \alpha \rangle \tau & \sim_{\text{lv}} \langle (\lambda x.t | F) | y = \lambda x.t | \rangle \tau \quad \text{if} \quad \tau = \tau_0[\alpha = \mu y.(y|F)\tau]\tau_1 \\
& \left\{ \begin{array}{l}
\langle \lambda x.t | F | \rangle \tau \\
\langle \lambda x.t | F \rangle \tau \\
\end{array} \quad \text{if} \quad \tau = \tau_0[\alpha = F]\tau \land [x=V] \notin \tau \\
\end{array}
\hline
\end{array}
\]
The first two cases of the abstract machine are straightforward. If a variable, which is surrounded by an applicative context, is bound to a value then that value is substituted. If the variable is bound to a computation, a switching of context occurs. To understand the next case, consider the state \( \langle x \alpha \rangle \tau \), where \( \tau \) is \( [x=V][\alpha = \tilde{\mu}y.(yF)\epsilon] \), we need to make sure that the substitution for \( x \) occurs before the substitution for \( \alpha \), that is, the next state should be \( \langle V \alpha \rangle \tau \) and not \( \langle x \rangle \tau \) \( [y=x] \). That explains why we first check if \( x \) is bound to a value. Consider now state \( \langle x \alpha \rangle [x=\mu\beta.c][\alpha = \tilde{\mu}y.(yF)] \), we need to make sure that the substitution for \( y \) occurs before switching to \( c \). Thus, the next state should be \( \langle x \rangle \tau \) \( [y = x][x=\mu\beta.c][\alpha = \tilde{\mu}y.(yF)] \).

States of the abstract machine are translated into the \( \lambda_{lv} \) calculus as follows:

\[
\begin{align*}
(c\tau)^\circ &= \tau^\circ[c] \\
\epsilon^\circ &= \Box \\
([x = \mu\alpha.c_1]\tau)^\circ &= \tau^\circ([\mu\alpha.c_1|\tilde{\mu}x,\Box]) \\
([x = V]\tau)^\circ &= \tau^\circ[\Box[x \leftarrow V]] \\
([\alpha = F]\tau)^\circ &= \tau^\circ[\Box[\alpha \leftarrow F]] \\
([\alpha = \mu\beta.(yF)\tau']\tau)^\circ &= \tau^\circ[\Box[\alpha \leftarrow \mu\beta.(\tau')^\circ(yF)]]
\end{align*}
\]

**Proposition LV.3.**

(i) if \( st \vdash_{lv} st' \) then \( (st)^\circ \leftarrow_{0/1} (st')^\circ \);  
(ii) if \( c \vdash_{lv} c' \) then, for any binding \( \tau \), there exists a state \( (c'' \tau_0) \) such that \( c \vdash_{lv} c'' \tau_0 \) and \( c' \equiv (c'' \tau_0)^\circ \).

**Proof.** (i) Follows from the fact that the translation of \( c\tau \) is of the form \( C_{lv}[c\sigma] \) for some meta-context \( C_{lv} \) and some substitution \( \sigma \).

More precisely, the first rule corresponds to an identity in case \( x \) is bound to a computation, otherwise it corresponds to \( \tilde{\mu}_v \). The second rule corresponds to a \( \beta \) step; The third rule corresponds to a \( \mu_l \) step while the fourth rule is an identity. The fifth rule corresponds to a \( \mu_l \) step:

\[
\text{\(\tau_1^\circ((\mu\alpha.c|\tilde{\mu}x.\tau_0^\circ([x\|t\cdot E])))) \mapsto \tau_1^\circ[c|\alpha \leftarrow \tilde{\mu}x.\tau_0^\circ([x\|t\cdot E])]\)
\]

The sixth and seventh rules correspond to a \( \tilde{\mu}_v \) step (below, the case of the seventh rule):

\[
\begin{align*}
\tau^\circ[\tau_0^\circ((\lambda x.t\|\tilde{\mu}y.\tau'\circ([y\|F])))] &\mapsto \tau^\circ[\tau_0^\circ[\tau'\circ((\lambda x.t\|F)||y \leftarrow \lambda x.t)]]
\end{align*}
\]

The last rule corresponds to an identity. \( \Box \)

The restriction to the minimal case is easily obtained by remembering that once the single continuation variable \( * \) is used, there is no need to keep its binding. The classical case has to consider a state such as \( \langle \lambda x.\mu\delta.(z|\alpha)||\alpha \rangle[\alpha = \tilde{\mu}x.(xF)\epsilon] \), therefore, after having substituted for \( \alpha \) its binding needs to be maintained in place. Instead, in the minimal case, \( \delta \) and \( \alpha \) have to be the same, therefore, one would have: \( \langle \lambda x.\mu*.(z|\alpha)||\alpha \rangle[\alpha = \tilde{\mu}x.(xF)\epsilon] \), once the substitution
occurs the binding is deleted. This is captured by the rules below:

\[
\begin{align*}
\langle x \rangle \vdash \tau & \quad \vdash_{\text{mv}} \langle x \rangle F \vdash \tau' \quad \text{if } \tau = \tau_0 \upharpoonright \mu = \mu y. \langle y \rangle F \vdash \tau_1 \land [x = V] \not\in \tau \\
\langle \lambda x.t \rangle \vdash \tau & \quad \vdash_{\text{mv}} \begin{cases} 
\langle \lambda x.t \rangle F \vdash \tau' \quad \text{if } \tau = \sigma_0 \upharpoonright \mu = \mu y. \langle y \rangle F \vdash \tau_1 \\
\langle \lambda x.t \rangle F \vdash \tau_0 \tau' 
\end{cases} \quad \text{if } \sigma = \sigma_0 \upharpoonright \mu = \mu \vdash \tau' \\
\end{align*}
\]

Remark IV.4. The minimal restriction differs from the abstract machine of Garcia et al. [21], since the applicative context is kept separate from the binding context. This has the advantage that once a value is reached, the binding context does not need to be recognized and collected up to the nearest applicative context. This avoids copying and re-installing of bindings, as shown below. The execution of \( (\lambda x_1.\lambda x_2.\lambda x_3.x_2)t_1t_2t_3 \) (for simplicity we do not show the set \( X \) used to generate unique names) according to Garcia et al. is:

\[
\begin{align*}
\langle \square, (\lambda x_1.\lambda x_2.\lambda x_3.x_2)t_1t_2t_3 \rangle & \quad \Rightarrow \\
\langle \square, \langle \lambda x_1.\square \rangle t_1 o (\lambda x_2.\square)t_2, \lambda x_3.x_2 \rangle & \quad \Rightarrow \text{Bindings are copied} \\
\langle \square, \langle \lambda x_1.\square \rangle t_1 o (\lambda x_2.\square)t_2, \lambda x_3.x_2t_3 \rangle & \quad \Rightarrow \text{Bindings are re-installed} \\
\langle (\lambda x_1.\square)t_1 o (\lambda x_2.\square)t_2 o (\lambda x_3.\square)t_3, x_2 \rangle & \\
\end{align*}
\]

Our execution is:

\[
\begin{align*}
\langle \lambda x_1.\lambda x_2.\lambda x_3.\mu^*.(x_2 \parallel t \parallel *) \parallel t_1 \cdot t_2 \cdot t_3 \cdot * \rangle & \quad \vdash_{\text{mv}} \\
\langle \lambda x_3.\mu^*.(x_2 \parallel t \parallel *) \parallel t_3 \cdot * \rangle & \quad \vdash_{\text{mv}} x_2 = t_2 \parallel x_1 = t_1 \\
\langle \mu^*.(x_2 \parallel t \parallel *) \parallel * \rangle & \quad \vdash_{\text{mv}} x_3 = t_3 \parallel x_2 = t_2 \parallel x_1 = t_1 \\
\end{align*}
\]

This separation between the applicative context and the binding context is essential in the classical case, since the binding contexts should not be part of the captured context, as described above in Section 6.

8 Dual classical call-by-need in sequent form (\( \lambda_{\mu} \))

In call-by-need, the focus is on the consumer and goes to the producer on a need basis. This suggests a dual call-by-need which corresponds to focusing on the producer and going to the consumer on a need basis. To that end, we first extend the classical call-by-need calculus of the previous section, \( \lambda_{\mu} \), with the dual of the implication, the subtraction connective, and then build the dual classical call-by-need calculus by using duality constructions typical from \( \lambda\mu\mu\mu \)-calculi.

While \( \mu \) and \( \mu^* \) constructs are dual of each other, implicative constructions \( \lambda x.t \) and \( t \vdash E \) currently have no dual in \( \lambda_{\mu} \). We extend \( \lambda_{\mu} \) by adding constructions for the subtraction connective [10]. Subtraction was already considered in the setting of \( \lambda\mu\mu \) in Curien et al. [11]. We follow the notation introduced by Herbelin in his habilitation thesis [23]. Terms are extended with the construction \( v - e \) and contexts with \( \lambda x.e \). The corresponding reduction is:

\[
(\sim) \quad \langle v - e \parallel \lambda x.e \rangle \rightarrow \langle \mu x.(v \parallel e') \parallel e \rangle
\]

We can now present the classical call-by-need calculus extended with subtraction, \( \lambda_{\mu} \). The structural rules are obtained by instantiating \( \mathcal{V} \) and \( \mathcal{E} \) as:

\[
V^- = x \mid \lambda x.t \mid (V^- - e)
\]

16
its syntax is given as follows:

\[ E^- = F^- \upharpoonright \mu x.C^\mu([x|F^-]) \] with \( F^- = \alpha \upharpoonright v \cdot E^- \upharpoonright \tilde{\lambda} \alpha.e \)

The syntax for the language with subtraction is finally as follows (with \( c = \langle v|e \rangle \)):

\[
\begin{align*}
\text{meta-context} & \quad C ::= \Box \upharpoonright \langle \mu \alpha.c | \tilde{\mu}x.C \rangle \\
\text{linear term} & \quad V ::= x \upharpoonright V - e \upharpoonright \lambda x.v \\
\text{term} & \quad \nu ::= V \upharpoonright \mu \alpha.c \\
\text{applicative context} & \quad F ::= \alpha \upharpoonright v \cdot E \upharpoonright \tilde{\lambda} \alpha.e \\
\text{linear context} & \quad E ::= F \upharpoonright \tilde{\mu}x.C([x|F]) \\
\text{context} & \quad e ::= E \upharpoonright \tilde{\mu}x.c
\end{align*}
\]

Using the duality principles developed in \[11\], we obtain \( \lambda^-_w \) by dualizing \( \lambda^-_l \): The syntax of the calculus is obtained by dualizing \( \lambda^-_w \) syntax and its reductions are also obtained by duality: \( (\beta) \) and \( (-) \) are dual of each other while \( \mu_v \) and \( \tilde{\mu}_l \) are respectively turned into:

- the \( \mu \)-reduction associated with set \( E^-_n ::= \alpha \upharpoonright t \cdot E_n \upharpoonright \tilde{\lambda} \alpha.e \), written \( \mu_n \)
- the \( \tilde{\mu} \)-reduction associated with set \( V^-_l ::= W \upharpoonright \mu \alpha.e/n([W|\alpha]) \), with \( W ::= x \upharpoonright \lambda x.t \upharpoonright W - e \) (and \( C^\mu \) being the dual of \( C^\nu \)), written \( \tilde{\mu} \).

Since only linear contexts are substituted for context variables, as in call-by-name, but only on a needed basis, we call the resulting calculus lazy call-by-name. Its syntax is given as follows:

\[
\begin{align*}
\text{meta-context} & \quad C ::= \Box \upharpoonright \langle \mu \alpha.C | \tilde{\mu}x.c \rangle \\
\text{linear context} & \quad E ::= \alpha \upharpoonright \tilde{\lambda} \alpha.e \upharpoonright t \cdot E \\
\text{context} & \quad e ::= E \upharpoonright \tilde{\mu}x.c \\
\text{linear term} & \quad W ::= x \upharpoonright \lambda x.t \upharpoonright W - e \\
\text{value} & \quad V ::= W \upharpoonright \mu \alpha.C([W|\alpha]) \\
\text{term} & \quad t ::= V \upharpoonright \mu \alpha.c
\end{align*}
\]

The four theories can be discriminated by the following command:

\[
c = \langle \mu \alpha.\langle \lambda x.\mu_.\langle \lambda y.x|\alpha \rangle |\alpha \rangle | \tilde{\mu}f.\langle \mu \beta.\langle f |t \cdot \beta \rangle | \tilde{\mu}x_1.\langle \mu \gamma.\langle f |s \cdot \gamma \rangle | \tilde{\mu}x_2.\langle x_1 |x_2 \cdot x_2 \cdot \delta \rangle |\rangle \rangle \rangle
\]

We call \( c_1 \) the command obtained by instantiating \( t \) and \( s \) to \( \lambda x.\lambda y.x \) and \( \lambda x.\lambda y.y \), respectively. Then \( c_1 \) evaluates to \( \langle \lambda x.\lambda y.x|\delta \rangle \) in lazy call-by-value and to \( \langle \lambda x.\lambda y.y|\delta \rangle \) in call-by-name. We call \( c_2 \) the command obtained by instantiating \( t \) and \( s \) to \( \lambda f.\lambda x.\mu\alpha.\langle f |x \cdot \alpha \rangle \) and \( \lambda x.x \). We now consider \( c_3 \) to be \( \langle \mu \gamma.\mu_\varepsilon.\langle f |\lambda x.\mu\alpha.\langle f |x \cdot \alpha \rangle |\delta \rangle \rangle \), where \( w \) does not occur free in \( c_1 \) and \( \gamma \) does not occur free in \( c_2 \). In call-by-name and lazy call-by-value, \( c_3 \) evaluates as \( c_1 \), up to garbage collection. However, \( c_3 \) evaluates to \( \langle \lambda f.\lambda x.\mu\alpha.\langle f |x \cdot \alpha \rangle |\delta \rangle \) in call-by-value, and to \( \langle I|\delta \rangle \) in lazy call-by-name, up to garbage collection. This can be generalized by
the following example, where we assume that $\alpha_1$ does not occur free in $c$ and $V$, and that $x_1$ does not occur free in $c'$ and $E$. If we define

$$c_0 \triangleq \langle \mu \alpha_1.c_1, \langle \mu \alpha_2.c_2 \rangle [\mu y.c] \rangle [\mu x_1.c_3] [\mu x_2.c_4] [\mu y.c] [\mu z.c]$$

then

$$c_0 \rightarrow \tau c_1' \beta \leftarrow E[x_2 \leftarrow \mu \beta.c']$$
$$c_0 \rightarrow \sigma c_1' \beta \leftarrow V[\alpha_2 \leftarrow \mu y.c]$$
$$c_0 \rightarrow \tau c_3' y \leftarrow \mu \alpha_2.c_2 [\mu y.c] [\mu x_1.c_3] [\mu x_2.c_4]$$
$$c_0 \rightarrow \tau c_4' \beta \leftarrow \mu x_2.c_4 [\mu y.c] [\mu x_1.c_3] [\mu x_2.c_4]$$

9 Conclusions and Future work

The advantage of studying evaluation order in the context of sequent calculus has shown its benefits: extending the calculus (both syntax and reduction theory) to the classical case simply corresponds to going from one context variable to many. The study has also suggested how to provide a call-by-need version of Parigot’s $\lambda\mu$-calculus, and in the minimal case, has led to a new notion of standard reduction, which applies the \textit{lift} and \textit{assoc} rule eagerly. In the minimal case, the single context variable, called $\star$, could be seen as the constant $t_p$ discussed in [65]. In the cited work, it is also presented how delimited control can be captured by extending $t_p$ to a dynamic variable named $t_p$. This suggests that one could use $t_p$ instead of $t_p$ to represent computations also in the minimal setting. Since evaluation goes under a $t_p$, it means that one would obtain a different notion of standard reduction, which would correspond to the one of Ariola et al. [3] and Maraist et al. [25].

A benefit of sequent calculus over natural deduction in both call-by-name and call-by-value is that the standard redex in the sequent calculus always occurs at the top of the command. In other words, there is no need to perform an unbounded search to reach the standard redex [2]; this search is embedded in the structural reduction rules. However, this does not apply to our call-by-need sequent calculus: the standard redex can be buried under an arbitrary number of bindings. This can be easily solved by considering a calculus with explicit substitutions. A command now becomes $\langle v|c|\tau$, where $\tau$ is a list of declarations. For example, the critical pair will be solved as: $\langle \mu a.c[\mu x.c']\tau \rightarrow c'[x = \mu a.c]\tau$ and the switching of context is realized by the rule: $\langle x|E\rangle \tau_0[x := \mu a.c]\tau_1 \rightarrow c[\alpha := \mu x.E]\tau_0\tau_1$. This will naturally lead us to developing abstract machines, which will be compared to the abstract machines of Garcia et al. [21] and Danvy et al. [13], inspired by natural deduction.

We have related the lazy call-by-value with subtraction to its dual. We plan to provide a simulation of lazy call-by-value in lazy call-by-name and vice-versa, without the use of subtraction. We are also interested in devising a complete set of axioms with respect to a classical extension of the call-by-need continuation-passing style of Okasaki et al. [28]. A natural development will then be to extend our lazy call-by-value and lazy call-by-name with delimited control. Following a suggestion by Danvy, we will investigate connections between our lazy call-by-name calculus and a calculus with futures [27]. At last, we want to better understand the underlying logic or type system.
