## Memo on Logics over Finite Trees

Sylvain Schmitz ENS Cachan, Université Paris-Saclay, France

We recall the syntax and semantics of two logics on finite trees: monadic second-order logic (MSO) and propositional dynamic logic (PDL). These are actually special cases of the same logics on finite relational structures, and we present the general framework.

## 1 Trees as Relational Structures

Relational Structures. We consider finite relational signatures  $\sigma = ((R_i)_{1 \leq i \leq n})$  where each relation symbol  $R_i$  has a fixed arity  $r_i > 0$ . A  $\sigma$ -structure is a tuple  $\mathfrak{M} = (|\mathfrak{M}|, (R_i^M)_{1 \leq i \leq n})$  where  $|\mathfrak{M}|$  is the domain and each  $R_i^{\mathfrak{M}}$  is an 'interpretation' of  $R_i$  as a relation in  $|\mathfrak{M}|^{r_i}$ ; when the particular structure is clear from the context, we omit the  $\mathfrak{M}$  superscripts in interpretation. A structure is finite if  $|\mathfrak{M}|$  is finite.

**Ranked Trees.** Recall that a (finite ordered) ranked tree t over some finite ranked alphabet  $\mathcal{F}$  can be seen as a partial function from  $\mathbb{N}_{>0}$  to  $\mathcal{F}$ . Let  $k \stackrel{\text{def}}{=} \max_{\mathcal{F}_i \neq \emptyset} i$  be the maximal arity in  $\mathcal{F}$ . We consider a finite set of atomic predicates A; typically  $A = \mathcal{F}$ , but in some applications one prefers  $2^A = \mathcal{F}$ . We shall use  $A = \mathcal{F}$  here.

Ranked trees t in  $T(\mathcal{F})$  can be seen as relational structures with domain Pos(t) over the signature  $(\downarrow_1, \ldots, \downarrow_k, (P_f)_{f \in \mathcal{F}})$ : we interpret the relations by

$$\downarrow_i \stackrel{\text{def}}{=} \{(p, pi) \in \operatorname{Pos}(t)^2\} \qquad \text{for all } 1 \leq i \leq k,$$

$$P_f \stackrel{\text{def}}{=} \{p \in \operatorname{Pos}(t) \mid t(p) = f\} \qquad \text{for all } f \in \mathcal{F}.$$

Other relational signatures are of course possible, for instance including

$$\downarrow \stackrel{\text{def}}{=} \{ (p, pi) \in \operatorname{Pos}(t)^2 \mid i \in \mathbb{N}_{>0} \} ,$$

$$\downarrow^* \stackrel{\text{def}}{=} \{ (p, pp') \in \operatorname{Pos}(t)^2 \mid p' \in \mathbb{N}_{>0}^* \} .$$

**Unranked Trees.** An unranked tree t over a finite alphabet  $\Sigma$  can similarly be seen as a relational structure with domain Pos(t) for the signature  $(\downarrow, \rightarrow, (P_a)_{a \in \Sigma})$ : we interpret the relations by

$$\downarrow \stackrel{\text{def}}{=} \{ (p, pi) \in \operatorname{Pos}(t)^2 \mid i \in \mathbb{N}_{>0} \} ,$$

$$\rightarrow \stackrel{\text{def}}{=} \{ (pi, p(i+1)) \in \operatorname{Pos}(t)^2 \mid i \in \mathbb{N}_{>0} \} ,$$

$$P_a \stackrel{\text{def}}{=} \{ p \in \operatorname{Pos}(t) \mid t(p) = a \}$$
 for all  $a \in \Sigma$ .

Again, other relational signature are possible.

## 2 Monadic Second-Order Logic & Co.

**Syntax.** Consider a finite signature  $\sigma = ((R_i)_{1 \le i \le n})$ . Let  $\mathcal{X}_1$  and  $\mathcal{X}_2$  be two infinite countable disjoint sets of first-order and second-order variables. The set of  $MSO(\sigma)$  formulæ is defined by the abstract syntax

$$\psi ::= R_i(x_1, \dots, x_{r_i}) \mid x = x' \mid x \in X \mid \neg \psi \mid \psi \land \psi \mid \exists x. \psi \mid \exists X. \psi$$

where  $1 \le i \le n$ ,  $x, x', x_1, \dots \in \mathcal{X}_1$ , and  $X \in \mathcal{X}_2$ . The set of FO( $\sigma$ ) formulæ is defined by removing second-order quantification and  $x \in X$  predicates:

$$\psi ::= R_i(x_1, \dots, x_{r_i}) \mid x = x' \mid \neg \psi \mid \psi \wedge \psi \mid \exists x \cdot \psi.$$

**Semantics.** Given a  $\sigma$ -structure  $\mathfrak{M} = (|\mathfrak{M}|, (R_i)_{1 \leq i \leq n})$  and two valuations  $\nu_1 \colon \mathcal{X}_1 \to |\mathfrak{M}|$  and  $\nu_2 \colon \mathcal{X}_2 \to 2^{|\mathfrak{M}|}$ , we say that  $\mathfrak{M}$  satisfies  $\psi$  and write  $\mathfrak{M} \models_{\nu_1,\nu_2} \psi$  in the following situations:

$$\mathfrak{M} \models_{\nu_1,\nu_2} R_i(x_1,\dots,x_{r_i}) \qquad \text{if } (\nu_1(x_1),\dots,\nu_1(x_{r_i})) \in R_i ,$$

$$\mathfrak{M} \models_{\nu_1,\nu_2} x = x' \qquad \text{if } \nu_1(x) = \nu_1(x') ,$$

$$\mathfrak{M} \models_{\nu_1,\nu_2} x \in X \qquad \text{if } \nu_1(x) \in \nu_2(X) ,$$

$$\mathfrak{M} \models_{\nu_1,\nu_2} \neg \psi \qquad \text{if } \mathfrak{M} \not\models_{\nu_1,\nu_2} \psi ,$$

$$\mathfrak{M} \models_{\nu_1,\nu_2} \psi \wedge \psi' \qquad \text{if } \mathfrak{M} \models_{\nu_1,\nu_2} \psi \text{ and } \mathfrak{M} \models_{\nu_1,\nu_2} \psi' ,$$

$$\mathfrak{M} \models_{\nu_1,\nu_2} \exists x.\psi \qquad \text{if } \exists w \in |\mathfrak{M}|, \mathfrak{M} \models_{\nu_1[x \mapsto w],\nu_2} \psi ,$$

$$\mathfrak{M} \models_{\nu_1,\nu_2} \exists X.\psi \qquad \text{if } \exists S \subseteq |\mathfrak{M}|, \mathfrak{M} \models_{\nu_1,\nu_2[X \mapsto S]} \psi .$$

**Examples on Unranked Trees.** Over finite unranked trees and the signature  $(\downarrow, \rightarrow, (P_a)_{a \in \Sigma})$ , one typically defines the following first-order formulæ:

$$\operatorname{root}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (y \downarrow x) \\ \operatorname{first}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (y \to x) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{last}(x) \stackrel{\operatorname{def}}{=} \neg \exists y (x \to y) \\ \operatorname{l$$

and the following MSO formulæ:

$$x \downarrow^* y \stackrel{\text{def}}{=} \forall X. (x \in X \land (\forall z \forall z' (z \in X \land z \downarrow z' \Rightarrow z' \in X)) \Rightarrow y \in X)$$
$$x \to^* y \stackrel{\text{def}}{=} \forall X. (x \in X \land (\forall z \forall z' (z \in X \land z \to z' \Rightarrow z' \in X)) \Rightarrow y \in X) .$$

Finally, we say that a tree t satisfies  $\psi$  if there exist  $\nu_1$  and  $\nu_2$  such that  $t \models_{\nu_1,\nu_2} \psi$ , and we define the language of  $\psi$  as  $L(\psi) \stackrel{\text{def}}{=} \{t \in T(\Sigma) \mid \exists \nu_1, \nu_2, t \models_{\nu_1,\nu_2} \psi\}$ .

## 3 Propositional Dynamic Logic

Here we assume that all the relational symbols in  $\sigma = ((R_i)_{1 \le i \le n}, (P_p)_{p \in A})$  to be either binary for all  $(R_i)_{1 \le i \le n}$  or unary for all  $(P_p)_{p \in A}$ . The definitions can actually be extended to higher arities.

**Syntax.** There are two sorts of PDL formulæ: node formulæ hold in particular points of the structure (called 'worlds' in the modal logic literature), while path formulæ hold between points. We present here a version of PDL with converse

$$\varphi ::= \top \mid p \mid \neg \varphi \mid \varphi \wedge \varphi \mid \langle \pi \rangle \varphi , \qquad \text{(node formulæ)}$$

$$\pi ::= R_i \mid \varphi? \mid \pi^{-1} \mid \pi; \pi \mid \pi + \pi \mid \pi^*, \qquad \text{(path formulæ)}$$

where p ranges over A and  $1 \le i \le n$ .

**Semantics.** A node formula  $\varphi$  is satisfied in a world  $w \in |\mathfrak{M}|$  of a  $\sigma$ -structure  $\mathfrak{M} = (|\mathfrak{M}|, (R_i)_{1 \leq i \leq n}, (P_p)_{p \in A})$ , denoted  $\mathfrak{M}, w \models \varphi$ , in the following situations:

 $\mathfrak{M}, w \models \top$  always,

 $\mathfrak{M}, w \models p$  if  $w \in P_p$ ,

 $\mathfrak{M}, w \models \neg \varphi$  if  $\mathfrak{M}, w \not\models \varphi$ ,

 $\mathfrak{M}, w \models \varphi \land \varphi'$  if  $\mathfrak{M}, w \models \varphi$  and  $\mathfrak{M}, w \models \varphi'$ ,

 $\mathfrak{M}, w \models \langle \pi \rangle \varphi$  if  $\exists w' \in |\mathfrak{M}|, \mathfrak{M}, w, w' \models \pi$  and  $\mathfrak{M}, w' \models \varphi'$ .

Similarly, a path formula  $\pi$  is satisfied between two worlds w and w' of  $\mathfrak{M}$ , denoted  $\mathfrak{M}, w, w' \models \pi$ , in the following situations:

 $\mathfrak{M}, w, w' \models R_i$  if  $(w, w') \in R_i$ ,

 $\mathfrak{M}, w, w' \models \varphi$ ? if w = w' and  $\mathfrak{M}, w \models \varphi$ ,

 $\mathfrak{M}, w, w' \models \pi^{-1}$  if  $\mathfrak{M}, w', w \models \pi$ ,

 $\mathfrak{M}, w, w' \models \pi; \pi'$  if  $\exists w'' \in |\mathfrak{M}|, \mathfrak{M}, w, w'' \models \pi$  and  $\mathfrak{M}, w'', w' \models \pi'$ ,

 $\mathfrak{M}, w, w' \models \pi + \pi'$  if  $\mathfrak{M}, w, w' \models \pi$  or  $\mathfrak{M}, w, w' \models \pi'$ ,

$$\mathfrak{M}, w, w' \models \pi^*$$
 if  $\exists n \in \mathbb{N}, \exists w_1 = w, w_2, \dots, w_{n-1}, w_n = w' \in |\mathfrak{M}|, \forall 1 \leq j < n, \mathfrak{M}, w_j, w_{j+1} \models \pi$ .

 $Satisfaction\ Sets.$  Alternatively, we can define the semantics through  $satisfaction\ sets:$ 

$$\llbracket \varphi \rrbracket_{\mathfrak{M}} \stackrel{\text{def}}{=} \{ w \in |\mathfrak{M}| \mid \mathfrak{M}, w \models \varphi \} \qquad \llbracket \pi \rrbracket_{\mathfrak{M}} \stackrel{\text{def}}{=} \{ (w, w') \in |\mathfrak{M}|^2 \mid \mathfrak{M}, w, w' \models \pi \} .$$

One obtains for instance

$$[\![\langle \pi \rangle \varphi]\!]_{\mathfrak{M}} = ([\![\pi]\!]_{\mathfrak{M}})^{-1} ([\![\varphi]\!]_{\mathfrak{M}}) , \qquad [\![\pi^*]\!]_{\mathfrak{M}} = [\![\pi]\!]_{\mathfrak{M}}^* .$$

Box Modalities. Finally, let us mention that the dual of the 'diamond'  $\langle \pi \rangle$  is the 'box'  $[\pi]\varphi \stackrel{\text{def}}{=} \neg \langle \pi \rangle \neg \varphi$ :

$$\mathfrak{M}, w \models [\pi] \varphi \text{ if } \forall w' \in |\mathfrak{M}|, \ \mathfrak{M}, w, w' \models \pi \text{ implies } \mathfrak{M}, w' \models \varphi .$$

**Examples on Unranked Trees.** Over finite unranked trees and the signature  $(\downarrow, \rightarrow, (P_a)_{a \in \Sigma})$ , one typically defines the following path formulæ

$$\uparrow \stackrel{\mathrm{def}}{=} \downarrow^{-1} \qquad \qquad \leftarrow \stackrel{\mathrm{def}}{=} \rightarrow^{-1}$$

and node formulæ

$$\begin{array}{ll} \operatorname{root} \stackrel{\mathrm{def}}{=} [\uparrow] \bot & \operatorname{leaf} \stackrel{\mathrm{def}}{=} [\downarrow] \bot \\ \operatorname{first} \stackrel{\mathrm{def}}{=} [\leftarrow] \bot & \operatorname{last} \stackrel{\mathrm{def}}{=} [\rightarrow] \bot \end{array}$$

Finally, we say that a tree t satisfies  $\varphi$ , denoted  $t \models \varphi$ , if it satisfies it at the root, i.e.  $\varphi, \varepsilon \models \varphi$ . The language of  $\varphi$  is  $L(\varphi) \stackrel{\text{def}}{=} \{t \in T(\Sigma) \mid t \models \varphi\}$  the set of trees that satisfy the formula.
