Abstract

We prove that five ways to define entry A086377 in the OEIS do lead to the same integer sequence.

1. Introduction

In September of 2003 Benoit Cloitre contributed a sequence to the On-Line Encyclopedia of Integer Sequences [4], defined by him as $a_1 = 1$, and for $n \geq 2$ by

$$a_n = \begin{cases} 
a_{n-1} + 2 & \text{if } n \text{ is in the sequence}, 
a_{n-1} + 2 & \text{if } n \text{ and } n-1 \text{ are not in the sequence}, 
a_{n-1} + 3 & \text{if } n \text{ is not in the sequence, but } n-1 \text{ is in the sequence}. 
\end{cases} \quad (1)$$

The first 25 values of this sequence are

1, 4, 6, 8, 11, 13, 16, 18, 21, 23, 25, 28, 30, 33, 35, 37, 40, 42, 45, 47, 49, 52, 54, 57, 59.

The purpose of this paper is to prove equivalence of five ways to define this integer sequence, most of them already conjecturally stated in the OEIS article on A086377. Besides a simplified recursion, the alternatives involve statements in terms of a morphic sequence, of a Beatty sequence, and of approximation properties linking a classical continued fraction of $\frac{4}{\pi}$ to that of $\sqrt{2}$.

\footnote{Supported by the ANR project ‘Dyna3S’ (ANR-13-BS02-0003).}
2. The theorem

**Theorem 1.** The following five definitions produce the same integer sequence:

(a) defined by \(a_1 = 1\) and for \(n \geq 2\):

\[
a_n = \begin{cases} 
    a_{n-1} + 2 & \text{if } n \text{ is in the sequence,} \\
    a_{n-1} + 2 & \text{if } n \text{ and } n-1 \text{ are not in the sequence,} \\
    a_{n-1} + 3 & \text{if } n \text{ is not in the sequence, but } n-1 \text{ is in the sequence;}
\end{cases}
\]

(b) defined by \(b_1 = 1\) and for \(n \geq 2\):

\[
b_n = \begin{cases} 
    b_{n-1} + 2 & \text{if } n-1 \text{ is not in the sequence,} \\
    b_{n-1} + 3 & \text{if } n-1 \text{ is in the sequence;}
\end{cases}
\]

(c) for \(n \geq 1\) defined as the position of the \(n\)-th zero in the fixed point of the morphism

\[
\phi : \begin{cases} 
    0 \mapsto 011 \\
    1 \mapsto 01
\end{cases}
\]

(d) defined by \(d_n = \lfloor (1 + \sqrt{2}) \cdot n - \frac{1}{2} \sqrt{2} \rfloor\) for \(n \geq 1\);

(e) defined by \(e_n = \lfloor r_n \rfloor = \lfloor r_n + \frac{1}{2} \rfloor\), with \(r_1 = \frac{4}{\pi}\) and \(r_{n+1} = \frac{n^2}{r_n - (2n - 1)}\) for \(n \geq 1\).

At first we found it hard to believe the equivalence of these definitions, but a verification of the first 130000 terms \((a_{130000} = 313847)\) convinced us to look for proofs.

3. Simplification and a morphic sequence

To show that \((b_n)\) defines the same sequence as \((a_n)\), simply note that \(a_n - a_{n-1} \geq 2\) for all \(n\): hence if \(n\) is in the sequence then \(n-1\) is not, and we can combine the first two cases in Equation (1).

In a comment to sequence A086377, Clark Kimberling asked if the integers in this sequence coincide with the positions of the zeroes in sequence A189687, which is the fixed point of the substitution

\[
\phi : \begin{cases} 
    0 \mapsto 011 \\
    1 \mapsto 01
\end{cases}
\]
defining the sequence \((c_n)\) in the Theorem. It is not hard to see that this indeed produces the same as sequence \((b_n)\); repeatedly applying the morphism \(\phi\) to 0 produces after a few steps the initial segment

\[0110101101101101101101101101101101101101101101101101101101101\cdots.\]

The position \(c_n\) of the \(n\)-th zero is 2 ahead of \(c_{n-1}\) precisely when the latter is followed by a single 1, that is, when there is a 1 at position \(n-1\), and it is 3 ahead of \(c_{n-1}\) if that zero is followed by 11, which means that there was a 0 at position \(n-1\). Thus the rule is exactly that defining \((b_n)\).

4. Beatty sequence

Every pair of real numbers \(\alpha\) and \(\beta\) determines a Beatty sequence by

\[B(\alpha, \beta)_n := \lfloor n\alpha + \beta \rfloor, \quad n = 1, 2, \ldots.\]

The numbers \(\alpha\) and \(\beta\) also determine sequences by

\[St(\alpha, \beta)_n := \lfloor (n+1)\alpha + \beta \rfloor - \lfloor n\alpha + \beta \rfloor, \quad n = 1, 2, \ldots,
\]

which is a Sturmian sequence (of slope \(\alpha\)), over the alphabet \(\{0, 1\}\), provided that \(0 \leq \alpha < 1\).

Thus Sturmian sequences are first differences of Beatty sequences (when \(0 \leq \alpha < 1\)), but Beatty sequences and Sturmian sequences are also linked in another way.

**Lemma 1.** Let \(\alpha > 1\) be irrational, and let \((s_n)_{n \geq 1}\) be given by \(s_n = St(\frac{1}{\alpha}, -\frac{\beta}{\alpha})_n\), for some real number \(\beta\) with \(\alpha + \beta > 1\) and such that \(k\alpha + \beta \notin \mathbb{Z}\) for all positive integers \(k\). Then \(B(\alpha, \beta)\) is the sequence of positions of 1 in \((s_n)\).

**Proof.** This is a generalization of Lemma 9.1.3 in [1], from homogeneous to inhomogeneous Sturmian sequences. The proof also generalizes:

there exists \(k \geq 1\) : \(n = \lfloor k\alpha + \beta \rfloor\) if and only if

there exists \(k \geq 1\) : \(n \leq k\alpha + \beta < n + 1\) if and only if

there exists \(k \geq 1\) : \(\frac{n - \beta}{\alpha} \leq k < \frac{n + 1 - \beta}{\alpha}\) if and only if

there exists \(k \geq 1\) : \(\left\lfloor \frac{n - \beta}{\alpha} \right\rfloor = k - 1\) and \(\left\lfloor \frac{n - \beta + 1}{\alpha} \right\rfloor = k\) if and only if

\[\left\lfloor \frac{n + 1 - \beta}{\alpha} \right\rfloor - \left\lfloor \frac{n - \beta}{\alpha} \right\rfloor = 1\] if and only if

\[St(\frac{1}{\alpha}, -\frac{\beta}{\alpha})_n = 1.\]
Our goal in this section is to prove that \((c_n) = (d_n)\). Let \(\psi\) be the morphism 
\[
\begin{align*}
\psi : \{0 &\rightarrow 10 \\
1 &\rightarrow 100
\end{align*}
\]
and let \(w\) be the fixed point. Then 
\[w = 10010101001010010010100101001010010101001010010100 \cdots,
\]
which is obtained by exchanging 0s and 1s in the fixed point of \(\phi\), i.e., \(\psi = E\phi E\), with \(E\) the exchange morphism given by \(E(0) = 1, E(1) = 0\). So the positions of 0 in the fixed point of \(\phi\) correspond to the positions of 1 in the fixed point \(w\) of \(\psi\).

Let \(\alpha_d = 1 + \sqrt{2}\) and \(\beta_d = -\frac{1}{2}\sqrt{2}\); then \(d_n = B(\alpha_d, \beta_d)\) for \(n \geq 1\).

Applying Lemma 1, we deduce that \(d_n\) also equals the position of the \(n\)-th 1 in the Sturmian sequence \(St(\alpha, \beta)\), generated by \(\alpha = \frac{1}{\alpha_d} = \sqrt{2} - 1, \beta = \frac{-\beta_d}{\alpha_d} = 1 - \frac{1}{2}\sqrt{2}\).

Lemma 2. \(St(\sqrt{2} - 1, 1 - \frac{1}{2}\sqrt{2}) = w\).

Proof. This was already proved by Nico de Bruijn in 1981 ([2]), where it is the main example. See also Lemma 2 in [6]. Note, however, that our Sturmian sequences start at \(n = 1\).

For a ‘modern’ proof as suggested by [3] Section 4, let \(\psi_1\) and \(\psi_2\) be the elementary morphisms given by \(\psi_1(0) = 01, \psi_1(1) = 0, \) and \(\psi_2(0) = 10, \psi_2(1) = 0\). Then \(\psi = \psi_2\psi_1 E\). This implies that the fixed point \(w\) of \(\psi\) is a Sturmian word (see [3] Corollary 2.2.19). To find its parameters \((\alpha, \beta)\), use the 2D fractional linear maps that describe how the parameters of a Sturmian word change when one applies an elementary morphism. For Sturmian words starting at \(n = 0\), the maps for \(E, \psi_1\) and \(\psi_2\) are the composition 
\[
T_{0}(x, y) = (1-x, 1-y), \quad T_{1}(x, y) = \left(\frac{1-x}{2-x}, \frac{1-y}{2-x}\right), \quad T_{2}(x, y) = \left(\frac{1-x}{2-x}, \frac{2-x-y}{2-x}\right).
\]

The change of parameters by applying \(\psi\) is therefore the composition 
\[
T_{210}(x, y) := T_{2}T_{1}T_{0}(x, y) = \left(\frac{1}{2+x}, \frac{2+x-y}{2+x}\right).
\]
But the parameters \(\alpha\) and \(\beta\) of \(w\) do not change when one applies \(\psi\). This means that \((\alpha, \beta)\) is a fixed point of \(T_{210}\), and one easily computes \(\alpha = \sqrt{2} - 1\), and then \(\beta = \frac{1}{2}\sqrt{2}\). Since our Sturmian words start at \(n = 1\), we have to subtract \(\alpha\) from \(\beta\) and obtain that \(w = St(\sqrt{2} - 1, 1 - \frac{1}{2}\sqrt{2})\). \(\square\)

---

\(^2\)Actually there is a subtlety here involving the ceiling representation of a Sturmian sequence, but that does not apply in our case since \(\beta \notin \mathbb{Z}\alpha + \mathbb{Z}\).
5. Converging recurrence

In a comment to entry A086377, Joseph Biberstine conjectured a beautiful connection with the infinite continued fraction expansion

\[
\frac{4}{\pi} = 1 + \frac{1^2}{3 + \frac{2^2}{5 + \frac{3^2}{7 + \frac{4^2}{9 + \frac{5^2}{11 + \ddots}}}}},
\]

derived from the arctangent function expansion. If we define \( R_n \) for \( n \geq 1 \) by

\[
R_n = 2n - 1 + \frac{n^2}{2n + 1 + \frac{(n + 1)^2}{2n + 3 + \frac{(n + 2)^2}{2n + 5 + \frac{(n + 3)^2}{\ddots}}}},
\]

then \( R_1 = 4/\pi \) and \( R_n = 2n - 1 + \frac{n^2}{R_{n+1}} \). We see that

\[
\frac{R_n}{n} \cdot \frac{R_{n+1}}{n+1} = \frac{2n - 1}{n} \cdot \frac{R_{n+1}}{n+1} - \frac{n^2}{n(n+1)} = 0.
\]

This implies that if \( R_n/n \) converges, for \( n \to \infty \), then it does so to a (positive) zero of \( x^2 - 2x - 1 \), that is, to \( 1 + \sqrt{2} \); cf. Lemma 3 below.

We consider now, conversely and slightly more generally, for any real \( h \geq 1 \), a sequence of positive numbers \( r_n \) satisfying

\[
r_n = hn - 1 + \frac{n^2}{r_{n+1}} \tag{2}
\]

for \( n \geq 1 \). We first show that this sequence is unique, i.e., there is a unique \( r_1 > 0 \) such that \( r_n > 0 \) for all \( n \geq 1 \), and give estimates for its terms.

**Lemma 3.** For each \( h \geq 1 \), there is a unique sequence of positive real numbers \( (r_n)_{n \geq 1} \) satisfying the recurrence \( (2) \). Moreover, we have for this sequence, for all \( n \geq 1 \),

\[
0 < r_n - an + c < \frac{(\alpha - c)(c - 1)}{\alpha n} \tag{3}
\]

with \( \alpha = \frac{h + \sqrt{h^2 + 4}}{2} \) and \( c = \frac{1 + \alpha}{2(\alpha - h)} = \frac{1}{2} + \frac{h + 2}{2\sqrt{h^2 + 4}} \).
Proof. Let \( f_n(x) = hn - 1 + n^2/x \). Suppose that a sequence of positive numbers \( r_n \) satisfies (2), i.e., that \( f_n(r_{n+1}) = r_n \) for all \( n \geq 1 \). Then we have \( r_n > hn - 1 \) and thus \( r_n < (h + 1/h)n \) for all \( n \geq 1 \). We deduce that there exists some \( \delta > 0 \) and \( N \geq 1 \) such that \( r_n > (h + \delta)n \) for all \( n \geq N \). Suppose that there is another sequence of positive numbers \( \tilde{r}_n \) satisfying (2). Since \( |f'_n(x)| = |n/x|^2 < 1/(h + \delta) \) for all \( x > (h + \delta)n \), we have

\[
|r_n - \tilde{r}_N| = |f_N f_{N+1} \cdots f_{n-1}(r_n) - f_N f_{N+1} \cdots f_{n-1}(\tilde{r}_n)| < \frac{n/h}{(h + \delta)^{n-N}}
\]

for all \( n \geq N \), hence \( r_N = \tilde{r}_N \), which implies that \( r_n = \tilde{r}_n \) for all \( n \geq 1 \).

Next we show that

\[
f_n\left(\alpha(n+1) - c\right) < \alpha n - c + \frac{(\alpha - c)(c-1)}{\alpha n}
\]

and

\[
f_n\left(\alpha(n+1) - c + \frac{(\alpha - c)(c-1)}{(n+1)\alpha}\right) > \alpha n - c.
\]

Indeed, using that \( \alpha^2 = ha + 1 \) and \( 2ac - hc = 1 + \alpha \), we have

\[
(\alpha + \alpha - c) f_n\left(\alpha(n+1) - c\right) = (hn - 1)(an + \alpha - c) + n^2
\]

\[
= (ha + 1)n^2 + (ha - hc - \alpha)n - (\alpha - c)
\]

\[
< \alpha^2 n^2 + (\alpha^2 - 2ac)n - (\alpha - c) + \frac{(\alpha - c)^2(c-1)}{an}
\]

\[
= (an + \alpha - c)\left(an - c + \frac{(\alpha - c)(c-1)}{\alpha n}\right),
\]

and

\[
\left(\alpha + \alpha - c + \frac{(\alpha - c)(c-1)}{\alpha(n+1)}\right)(an - c)
\]

\[
< \alpha^2 n^2 + (\alpha^2 - 2ac)n - (\alpha - c) - \frac{c(\alpha - c)(c-1)}{\alpha(n+1)}
\]

\[
< (ha + 1)n^2 + (ha - hc - \alpha)n - (\alpha - c) - \frac{(\alpha - c)(c-1)}{\alpha(n+1)}
\]

\[
< (hn - 1)\left(\alpha n + \alpha - c + \frac{(\alpha - c)(c-1)}{\alpha(n+1)}\right) + n^2
\]

\[
= \left(\alpha n + \alpha - c + \frac{(\alpha - c)(c-1)}{\alpha(n+1)}\right) f_n\left(\alpha(n+1) - c + \frac{(\alpha - c)(c-1)}{\alpha(n+1)}\right).
\]

As \( f_n \) is monotonically decreasing for \( x > 0 \), we deduce that

\[
0 < f_n(x) - an + c < \frac{(\alpha - c)(c-1)}{an}
\]
for all \( x \) with \( 0 \leq x - \alpha(n+1) + c \leq \frac{(\alpha-c)(c-1)}{\alpha(n+1)} \). Then we also have
\[
0 < f_nf_{n+1} \cdots f_{n+k-1} (\alpha(n+k) - c + x) - \alpha n + c < \frac{(\alpha-c)(c-1)}{\alpha n}
\]
for all \( k, n \geq 1 \), \( 0 \leq x - \alpha(n+k) + c \leq \frac{(\alpha-c)(c-1)}{\alpha(n+k)} \). As \( f_n \) is contracting for \( x \geq \alpha(n+1)-c \), the intervals \([f_1f_2 \cdots f_n(\alpha(n+1)-c), f_1f_2 \cdots f_n(\alpha(n+1)-c+\frac{(\alpha-c)(c-1)}{\alpha(n+1)})]\) converge to a point \( r_1 \). Then the numbers \( r_n \) given by (2) satisfy (3) for all \( n \geq 1 \).

By the first paragraph of the proof, this is the unique sequence of positive numbers satisfying (2).

Now consider when \( \alpha n - c + \frac{1}{2} \) is close to \([\alpha n - c + \frac{1}{2}]\). Let \( p_k/q_k \) be the convergents of the regular continued fraction \( \alpha = [h; h, \ldots] \), i.e., \( q_0 = 0 \), \( q_1 = 1 \), \( q_{k+1} = hq_k + q_{k-1} \) for \( k \geq 1 \), \( p_k = q_{k+1} \). Then we have
\[
q_k = \frac{\alpha^{k+1} + (-1)^k/\alpha^{k+1}}{\alpha+1/\alpha}
\]
and thus
\[
q_k \alpha - p_k = \frac{(-1)^k}{\alpha^{k+1}}.
\]

**Lemma 4.** Let \( h \) be a positive integer and \( \alpha = \frac{h + \sqrt{h^2+4}}{2} \). Then we have
\[
[\alpha n] - \alpha n = \begin{cases} 
\frac{j}{\alpha^{2k}} & \text{if } n = jq_{2k-1}, k \geq 1, 1 \leq j < \alpha^{2k}, \\
(\alpha-1)/\alpha^{2k+1} & \text{if } n = q_{2k-1} + q_{2k}, k \geq 0, \\
(\alpha+1)/\alpha^{2k+2} & \text{if } n = q_{2k+1} - q_{2k}, k \geq 0,
\end{cases}
\]
and \( n([\alpha n] - \alpha n) \geq 1 \) for all other \( n \geq 1 \).

**Proof.** The formulas for \( n = jq_{2k-1}, n = q_{2k-1} + q_{2k} \) and \( n = q_{2k+1} - q_{2k} \) are immediate from (1). By [7], Ch. 2, §5, Theorem 2], we have \( n([\alpha n] - \alpha n) \geq 1 \) for all \( n \geq 1 \) that are not of the form \( jq_k, 1 \leq j < \alpha/\sqrt{h}, q_k + q_{k-1} \) or \( q_k - q_{k-1} \). Since \( \alpha q_{2k} - [\alpha q_{2k}] = 1/\alpha^{2k+1}, \alpha(q_{2k} + q_{2k+1}) - [\alpha(q_{2k} + q_{2k+1})] = (\alpha-1)/\alpha^{2k+2} \) and \( \alpha(q_{2k} - q_{2k-1}) - [\alpha(q_{2k} - q_{2k-1})] = (\alpha+1)/\alpha^{2k+1} \), we have \([\alpha n] - \alpha n \geq 1/2 \) for \( n = jq_{2k}, n = q_{2k} + q_{2k+1} \) and \( n = q_{2k} - q_{2k-1} \). If moreover \( n \geq 2 \), then we have thus \( n([\alpha n] - \alpha n) \geq 1 \) for these \( n \) as well. Since \( q_0 + q_{-1} = 1 \), the case \( n = 1 \) has already been treated.

We obtain that
\[
n([\alpha n] - \alpha n) = \begin{cases} 
\frac{j^2(1-1/\alpha^{2k})}{\sqrt{h^2+4}} & \text{if } n = jq_{2k-1}, k \geq 1, 1 \leq j < \alpha^{2k}, \\
\frac{h - (\alpha-1)^2/\alpha^{4k+2}}{\sqrt{h^2+4}} & \text{if } n = q_{2k-1} + q_{2k}, k \geq 0, \\
\frac{h - (\alpha+1)^2/\alpha^{4k+4}}{\sqrt{h^2+4}} & \text{if } n = q_{2k+1} - q_{2k}, k \geq 0.
\end{cases}
\]
The worst case for \( n = q_{2k-1} + q_{2k} \) or \( n = q_{2k+1} - q_{2k} \) is given by \( n = q_{-1} + q_0 = 1 \), hence

\[
n([an] - an) \geq h + 1 - \alpha = 1 - \frac{1}{\alpha}
\]

for all \( n \geq 1 \) such that \( n \neq q_{2k-1} \) for all \( k \geq 1 \).

Now we come back to the case \( h = 2 \) and consider the distance of \( \alpha n - c + \frac{1}{2} \) to the nearest integer above \( \alpha n - c + \frac{1}{2} \). Note that \( c - \frac{1}{2} = \frac{1}{\sqrt{2}} \). We have

\[
2\left([an - \frac{1}{\sqrt{2}}] - an + \frac{1}{\sqrt{2}}\right) = 2\left([an - \frac{1}{\sqrt{2}}]\right) - 1 - \alpha(2n - 1) \\
\geq [\alpha(2n - 1)] - \alpha(2n - 1) > \frac{\alpha - 1}{2\alpha n},
\]

where we have used that \( q_{2k-1} \) is even for all \( k \geq 1 \); thus

\[
\left([an - \frac{1}{\sqrt{2}}]\right) - an + \frac{1}{\sqrt{2}} > \frac{\alpha - 1}{4\alpha n}.
\]

Since \((\alpha - c)(c - 1) = \frac{1}{4\alpha}\), we have

\[
an - \frac{1}{\sqrt{2}} < r_n + \frac{1}{2} < an - \frac{1}{\sqrt{2}} + \frac{1}{4\alpha n} < an - \frac{1}{\sqrt{2}} + \frac{\alpha - 1}{4\alpha n} < \left[an - \frac{1}{\sqrt{2}}\right]
\]

for all \( n \geq 1 \), thus \( d_n = e_n \). This completes the proof of Theorem 1.

We remark that \( h = 2 \) cannot be replaced by an arbitrary positive integer in the previous paragraph. For example, for \( h = 1 \), we have \( \alpha = \frac{1 + \sqrt{5}}{2} \), \( c = \frac{\alpha^2}{\sqrt{5}} \), \( \lfloor 137\alpha - c + \frac{1}{2} \rfloor = 220 \) and \( \lfloor r_{137} + \frac{1}{2} \rfloor = 221 \). However, computer simulations suggest that (for any \( h \)) we always have \( \lfloor \alpha n - c \rfloor = \lfloor r_n \rfloor \).

6. Acknowledgement

The authors gratefully acknowledge the organization of the Lorentz Center, Leiden, workshop Aperiodic Patterns in Crystals, Numbers and Symbols, in particular Robbert Fokkink, for bringing them together in a stimulating atmosphere.
